Experimental Section

1. Chemicals
The 20% Pt/C powder and 5 wt% Nafion were purchased from Alfa Aesar. Y(NO$_3$)$_3$·6H$_2$O, Pd(NO$_3$)$_2$·2H$_2$O, NaBH$_4$, polyvinylpyrrolidone (PVP), cetyltrimethylammonium bromide (CTAB), KOH, acetone and anhydrous ethanol were purchased from Sinopharm Chemical Reagent Co., Ltd. RuCl$_3$·nH$_2$O (Ru $\approx 37.0\% \pm 0.2\%$) was purchased from Shanghai Jiuyue Chemical Industry Co., Ltd. The ultrapure water used in this work was obtained from a Millipore water purification system ($\geq 18.25$ M$\Omega$ cm, Millipore SAS Corporation, France). Unless otherwise stated, all the above chemicals were used as received without further purification.

2. Synthetic methods

Synthesis of the Ru/Y(OH)$_3$ hybrid nanostructure. The Ru/Y(OH)$_3$ hybrid nanostructure was prepared via an in situ NaBH$_4$ reduction method. In detail, Y(NO$_3$)$_3$·6H$_2$O (0.06 g, 0.16 mmol), PVP (0.22 g), CTAB (0.36 g) and RuCl$_3$·nH$_2$O (0.33 g, 1.60 mmol) were first dissolved in deionized water (10 mL) and ultrasonicated to create a homogenous brown solution. After this solution was heated to 110 °C in an oil bath, 10 mL of aqueous NaBH$_4$ (containing 0.2 g NaBH$_4$) was dropwise added to this solution under continuous magnetic stirring. During this process, abundant hydrogen bubbles were formed and released; thus, a certain amount of ethanol is necessary to reduce the surface tension of the solution. The above solution was maintained at 110 °C for 2 h. Finally, a black precipitate was observed, which was centrifuged and separated several times using the mixture ethanol and acetone. The as-obtained product was dried at 60 °C in a vacuum oven overnight.

Synthesis of sole Ru NPs. The synthesis procedure for the Ru NPs was similar to that for the Ru/Y(OH)$_3$ nanostructure, but Y(NO$_3$)$_3$·6H$_2$O was not added.

Synthesis of the sole, flocculent Y(OH)$_3$ scaffold. The synthesis procedure for the Y(OH)$_3$ scaffold was similar to that for the Ru/Y(OH)$_3$ nanostructure, but RuCl$_3$·nH$_2$O was not added.

Synthesis of Ru/RGO. The synthesis procedure for the Ru/RGO was similar to that for the Ru/Y(OH)$_3$ nanostructure, but Y(NO$_3$)$_3$·6H$_2$O was replaced with RGO (10 mg).

3. Characterization
Transmission electron microscopy (TEM) was performed using a JEM-200CX microscope (Japan) with an accelerating voltage of 200 kV. The powder X-ray diffraction (XRD) patterns were collected on a D/max 2500VL/PC diffractometer (Japan) equipped with graphite-monochromatized Cu K$\alpha$ radiation ($\lambda = 1.54060$ Å), and corresponding scan range (20) was 5° to 90°. The related high resolution
transmission electron microscopy (HRTEM), X-ray energy-dispersive spectra (EDS),
elemental mapping, scanning transmission electron microscopy (STEM) and EDS line-
scan images were acquired using a JEOL-2100F apparatus at an accelerating voltage of
200 kV. The thermogravimetric data were collected on TGA NETZSCH STA449F3
instruments. Fourier transform infrared (FTIR) spectra were recorded on Tensor 27
(Bruker, Germany) at room temperature. Raman spectra were recorded on a JY HR 800
(France) instrument with an optical multichannel spectrometer Microdil 28 (Dilor)
equipped with a microscope. X-ray photoelectron spectroscopy (XPS) was conducted
using a scanning X-ray microprobe (PHI 5000 Verasa, ULAC-PHI, Inc.) with Al Kα
radiation. All energies were calibrated using the C1S peak (binding energy (BE) = 284.6
eV) as standard. Inductively coupled plasma (ICP) measurement was collected on an
Induction Coupled Plasma Quantometer (Jarrell-Ash 1100 + 2000). The
electrochemical impedance spectra (EIS) test was performed on a PGSTAT30/FRA2
system (Autolab, Netherlands) in 0.1 M KOH.

4. Electrochemical tests
The electrochemical HER experiments were conducted using a CHI 660D
electrochemical workstation with a typical three-electrode cell setup. Pt foil was used
as the counter electrode, Ag/AgCl (3 M KCl) acted as the reference electrode, and a
glassy carbon electrode (GCE) (3 mm in diameter) served as the working electrode in
0.1 M KOH. To prepare the catalyst ink, a certain amount of catalyst was mixed with
ethanol and ultrapure water (volume ratio of 1:3) and then ultrasonicated for
approximately 20 min to obtain a homogeneous catalyst ink (2 mg mL\(^{-1}\)). Then, 10 \(\mu\)L
of the above catalyst ink was pipetted onto the GCE surface and air dried, followed by
5 \(\mu\)L of a 1.0 wt% Nafion solution to protect the catalyst. All electrochemical
measurements were conducted in a \(\text{N}_2\)-saturated atmosphere at room temperature. Prior
to each electrochemical test, the modified electrodes were pretreated by performing
several CV cycles until the potential was stable to remove any possible surface
contamination. The CV tests were conducted using a potential window from -1.3 V to
-0.5 V (vs. Ag/AgCl), and polarization curves were obtained using a potential window
from -0.5 V to -1.3 V (vs. Ag/AgCl) after iR compensation with a scan rate of 5 mV s\(^{-1}\).
All potentials were referenced to reversible hydrogen electrode (RHE) values using
the equation \(E(\text{RHE}) = E_{\text{Ag}/\text{AgCl}} + 0.197 + 0.059pH\).
**Fig. S1** TEM images of the product when all of the NaBH₄ solution (10 mL) was added at one time.

**Fig. S2** TEM images of the product when NaBH₄ is replaced with N₂H₄·H₂O and other experimental conditions are kept constant.

**Fig. S3** TEM images of the product when Y(OH)₃ is replaced with RGO and other experimental conditions are kept constant.
Fig. S4 displays the component, morphology and crystal structure characterization of the as-prepared sole Y(OH)$_3$ counterpart. The EDS spectrum in Fig. S4a reveals the existence of Y and O elements in the product while C, Cu and Si elements originate from copper grid substrate. Fig. S4b-d show the TEM images of the product, from which large area flocculent product is observed. Fig. S4g and h show the STEM images of the flocculent product, which also indicate its 3D morphology. The HRTEM and SAED images reveal that no obvious lattice fringes (Fig. S4e) and diffraction spot or diffraction ring (Fig. S4f) can be found, indicative of amorphous feature of this product. Related XRD pattern also verified this result (Fig. S4i). Thus to identify the composition and structure characteristics of this product, thermo-gravimetric (TG) and fourier transform infrared (FT-IR) analyses are employed, and details are described in Fig. S5.
The TG curve in Fig. S5a demonstrates an attenuation of about 29.2% in mass during the decomposition process and finally remained at around 70.8%. Its decreased mass (480 µg) is exactly approximate to that of H₂O lost for Y(OH)₃, meaning a Y(OH)₃ structure for this product. The characteristic O-H stretching vibration at about 3540 cm⁻¹ in related FT-IR spectrum also confirmed its Y(OH)₃ construction (Fig. S5b).

Fig. S6 shows the component, morphology and crystal structure characterizations of the as-prepared sole Ru, from which large amounts of irregular Ru nanoparticles with an average size of about 4.8 nm and good crystallinity are observed.
**Fig. S7** EDS image of the Ru/Y(OH)$_3$ product.

**Fig. S8** (a-c) TEM and (d) STEM images of the Ru/Y(OH)$_3$ product.
Fig. S9 Diameter distribution image of the Ru nanoparticles in Ru/Y(OH)$_3$ product.

Fig. S10 The comparison of the XRD patterns of Ru/Y(OH)$_3$, Ru and Y(OH)$_3$.

In Fig. S10, the broad diffraction peak located at about 43° is assigned to the (101) or (002) planes of hexagonal Ru (JCPDS 65-1863) for Ru/Y(OH)$_3$ and sole Ru products, but nearly no obvious diffraction peak can be observed for the sole Y(OH)$_3$, indicative of the good crystallinity of Ru nanoparticles and amorphous feature of Y(OH)$_3$.

**Fig. S11** Comparison of the overpotential at 10 mA cm\(^{-2}\) (\(\eta_{10}\)) of the Ru/Y(OH)\(_3\) NHs and some recently reported representative electrocatalysts for HER in alkaline media. The derivation of these electrocatalysts are listed in References 1 in turn.

**Fig. S12** Mass activity of the Ru/Y(OH)\(_3\) NHs, Ru, Y(OH)\(_3\), Ru+Y(OH)\(_3\) and 20% Pt/C catalysts.

The mass activity value (A g\(^{-1}\)) in **Fig. S12** is calculated from the electrocatalyst loading \(m\) (0.28 mg cm\(^{-2}\)) and the measured current density \(j\) (mA cm\(^{-2}\)) at different overpotential (\(\eta\)) using the following formula:

\[
\text{Mass activity} = \frac{j}{m}
\]

**Fig. S13** Chronoamperometry test of the Ru/Y(OH)$_3$ NHs performed at the overpotential for 10 mA cm$^{-2}$. 

Fig. S14 (a) TEM, (b) size distribution, and (c, d) HRTEM images of the product after 20000 cycles durability test for Ru/Y(OH)$_3$.

Fig. S15 TEM image of the product after 20000 cycles durability test for Ru NPs.
Fig. S16 (a) HER polarization curves for the Ru/Y(OH)$_3$ NHs and Ru/RGO catalysts. (b) Cyclic voltammogram curves and (c) calculated electrochemical double-layer capacitances ($C_{dl}$) for the Ru/RGO catalyst. (d) The polarization curves of Ru, Ru/RGO and Ru/Y(OH)$_3$ normalized to electrochemical surface area. The inset of Fig. S16a is the durability test of Ru/RGO for 2000 cycles.

In Fig. S16a, Ru/RGO catalyst displays similar polarization curve as Ru/Y(OH)$_3$ due to the superior conductivity of RGO, but the durability of Ru/RGO is worse than that of the Ru/Y(OH)$_3$, indicating the important role of Y(OH)$_3$. Fig. S16d shows the polarization curves of Ru, Ru/RGO and Ru/Y(OH)$_3$ normalized to electrochemical surface area (ECSA), and the ECSA value ($cm_{ECSA}^2$) is calculated from $C_{dl}$ (mF cm$^{-2}$) and the specific capacitance value for a flat surface (40 $\mu$F cm$^{-2}$) using the following formula:

$$A (cm_{ECSA}^2) = C_{dl} \text{ (mF cm}^{-2})/40 \text{ (}$\mu$F cm$^{-2}$)$$

From Fig. S16d, slightly better onset potential is observed for the Ru/Y(OH)$_3$, proving the improvement effect of Y(OH)$_3$ in facilitating water dissociation kinetics.
Fig. S17 Cyclic voltammogram curves for (a) Ru and (c) Ru/Y(OH)$_3$ at various scan rates (0.02-0.2 V s$^{-1}$). The calculated $C_{dl}$ for the (b) Ru and (d) Ru/Y(OH)$_3$ catalysts. $C_{dl}$ can be used to represent the ECSA of the catalysts, and a larger ECSA indicates more active sites are available to promote the hydrogen evolution reaction.

Fig. S18 Comparisons of the (a) Y 3d and (d) fitted Ru 3p core level XPS spectra for sole Ru and Ru/Y(OH)$_3$ NHs.

Fig. 4c, 4d and S18 show the XPS results for Y(OH)$_3$, Ru and Ru/Y(OH)$_3$ NHs. As displayed in Fig. S18a, two Y 3d signal peaks located at 157.6 eV (3d 5/2) and 159.6 eV (3d 3/2) were observed for sole Y(OH)$_3$, which are consistent with the reported
values for Y(OH)$_3$.\textsuperscript{2} Furthermore, the Y 3d binding energy for the Ru/Y(OH)$_3$ NHs slightly shifted in the high-energy direction compared to that of sole Y(OH)$_3$, while the O 1s binding energy displayed a negative shift (\textbf{Fig. 4d}). In the Ru 3p core level spectra, the binding energy of the Ru/Y(OH)$_3$ NHs shifted in the high-energy direction compared to that of sole Ru (\textbf{Fig. 4c}). These shifts indicate partial electron transfers from both Y and Ru to O and electronic interactions between Ru and the hydroxyl groups in the Y(OH)$_3$ scaffold. \textbf{Fig. S18b} shows the deconvoluted Ru 3p spectra for sole Ru and Ru/Y(OH)$_3$ NHs. The predominant peak located at 462.1 eV is assigned to Ru(0), and the other peaks are affiliated with ruthenium oxide.\textsuperscript{3} The small amounts of ruthenium oxide are attributed to surface oxidation of the Ru NPs.
