Supporting Information

Dimanganese(III) porphyrin dication diradical and its transformation to a $\mu$-hydroxo porphyrin-oxophlorin heterodimer

Amit Kumar, Debangsu Sil, Mohammad Usman, and Sankar Prasad Rath*
Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur-208016, India

Instrumentation

UV-vis-NIR spectra were recorded on a PerkinElmer Lambda 950 UV-vis-NIR spectrometer. High resolution mass spectra (ESI) were recorded using a Waters Micromass QuattroMicro triple quadrupole mass spectrometer.

X-ray Structure Solution and Refinement.

Single-crystal X-ray data were collected at 100 K on a Bruker SMART APEX CCD diffractometer equipped with CRYO Industries low temperature apparatus and intensity data were collected using graphite-monochromated Mo Kα radiation ($\lambda=0.71073$ Å). The data integration and reduction were processed with SAINT software. An absorption correction was applied. The structure was solved by the direct method using SHELXS-97 and was refined on F2 by full-matrix least-squares technique using the SHELXL-2014 program package. Non-hydrogen atoms were refined anisotropically. In the refinement, hydrogen was treated as riding atoms using SHELXL default parameters.

Magnetic measurements.

Magnetic susceptibility data were collected using a Quantum Design MPMS SQUID magnetometer over the temperature range 5 to 300 K. The magnetic data were fitted, using the software PHI, to a model considering antiferromagnetic coupling between the unpaired spin ($S=1/2$) of the porphyrin $\pi$-cation radicals with the high-spin ($S=2$) manganese(III) centers, antiferromagnetic interaction between the radical spins ($S=1/2$) on the two porphyrin units of $\text{trans-2} \cdot \text{ClO}_4$ and interaction between two high-spin manganese centers in $\text{trans-2} \cdot \text{ClO}_4$. 

Electronic Supplementary Material (ESI) for ChemComm. This journal is © The Royal Society of Chemistry 2019
Presence of small amount of mononuclear Mn(III) impurity and temperature-independent paramagnetism have also been taken into account. Intermolecular interactions in trans-2ClO₄, have been excluded to keep the fitting model simple. In case of cis-3, the antiferromagnetic interactions between the two high-spin Mn(III) centers were considered for data fitting. Two set of data were collected over the temperature range of 5 to 300 K, by using applied magnetic fields of 0.1 T and corrected for diamagnetism using Pascal’s constant. The plots are shown in Figure 3 (see text). The value of g has been kept fixed at 2.00. The parameters obtained after fitting the magnetic data for trans-2ClO₄ are: $J_{\text{Mn-r}} = -49.12 \text{cm}^{-1}$, $J_{\text{Mn-Mn}} = 1.83 \text{ cm}^{-1}$, $J_{\text{Mn-r}} = -71.99 \text{ cm}^{-1}$, $D = -0.55 \text{ cm}^{-1}$, while the values for cis-3 are: $J = -30 \text{ cm}^{-1}$, $D = -9 \text{ cm}^{-1}$. The D values are similar to those observed for other manganese complexes reported in the literature.

**Computational Details.**

All geometry optimizations were initiated from the crystal structure coordinates of the $U$ form of trans-2ClO₄ and cis-3. All structures were optimized using the Gaussian 09, revision B.01, package. Geometry optimizations were carried out without any constraints and frequency calculations were also carried out on all optimized structures. Free energies were taken from the Gaussian frequencies and contain, zero-point, thermal and entropic corrections to the energy. Geometry optimizations have been carried out using the unrestricted hybrid density functional method B3LYP, along with unrestricted density functional method B97D, which incorporates a force-field-like pairwise dispersion correction developed by Grimme. The basis set was LANL2DZ for manganese atom and 6–31G** for carbon, nitrogen, chlorine, oxygen and hydrogen atoms, basis set combination labeled as BS1. $U$ form of trans-2ClO₄ was optimized as charge neutral species for three different spin multiplicities: (a) undectet (11) state (considering the radical centers of the two porphyrin units ferromagnetically coupled to the respective manganese center), (b) nonet (9) state (where the two radical spins are antiferromagnetically coupled to each other) and (c) septet (7) state (where the radical spins are antiferromagnetically coupled to the respective manganese center). Self-consistent reaction field (SCRF) method was applied in all the optimizations to consider solvent effect (chloroform was used as solvent) and frequency corrections ensured that there are no imaginary frequencies. Visualization of the molecular orbitals and the corresponding diagrams were done using the Chemcraft software.
Calculation and visualization of Fukui indices

The electron density was calculated at the B3LYP/BS1 level of theory for the neutral and anionic species. For the neutral and anionic species, the single point calculations were performed on the geometry taken from single crystal X-ray coordinates. The program “Multiwfn -- A Multifunctional Wavefunction Analyzer” (version 3.5)\textsuperscript{11} was used to subtract the electron densities and plot the corresponding isosurfaces using Chemcraft software. It is known that when the Fukui function, $f^+$, has a positive isosurface the nucleophilic attack is favored on that intramolecular region. In our case, the positive surface of $f^+$ function is distributed on the meso carbon of the dimanganese dication diradical dimer, trans-2•ClO$_4$, as compared to the corresponding meso carbon of its diiron analog\textsuperscript{12} where it is missing (vide infra). Furthermore, for the quantification of the $f^+$ values in atomic level, condensed Fukui function values were calculated using the atomic charges determined by the post-SCF Hirshfeld population analysis.\textsuperscript{13} The greater condensed Fukui function $f^+$ values indicate greater nucleophilicity of that particular atom, which is in good agreement with our experimental findings. The Hirshfeld atomic charges were used because of their little dependence on the basis set used. Hirshfeld charges $q$ and $f^+$ values are also summarized (vide infra).\textsuperscript{14}

Experimental Section:

Materials

The free ligands trans-$\text{-}1,2$-bis(meso-octaethylporphyrinyl)ethene and cis-$\text{-}1,2$-bis(meso-octaethylporphyrinyl)ethene was synthesized by modifying the literature method.\textsuperscript{15} Reagents and solvents were purchased from commercial sources and were purified by standard procedures before use.

Synthesis of trans-$\text{-}1$:

100 mg of trans-$\text{-}1,2$-bis(meso-octaethylporphyrinyl)ethene (0.091 mmol) was dissolved in 60 mL of chloroform. 300 mg of MnCl$_2$•4H$_2$O (1.56 mmol) dissolved in 10 mL of dry methanol was added to the above solution. The solution thus obtained was refluxed for 3 hours and then washed with 10% HCl (aq.) solution. The organic layer was separated, dried over anhydrous Na$_2$SO$_4$, and then evaporated to complete dryness. The solid product was purified by column chromatography on silica gel using chloroform:methanol (98:2) as eluent. Yield: 74 mg (63%).
UV–vis (dichloromethane) [$\lambda_{\text{max}}$, nm (ε, M$^{-1}$ cm$^{-1}$)]: 362 (3 × 10$^4$), 475(2 × 10$^4$), 580 (7 × 10$^3$), 628 (3.6 × 10$^3$).

**Synthesis of cis-1:**
100 mg of cis-1,2-bis(meso-octaethylporphyrinyl)ethene (0.091 mmol) was dissolved in 40 mL of chloroform. 300 mg of MnCl$_2$·4H$_2$O (1.56 mmol) dissolved in 8 mL of dry methanol was added to the above solution. The solution thus obtained was refluxed for 3 hours and then washed with 10% HCl (aq.) solution. The organic layer was separated, dried over anhydrous Na$_2$SO$_4$, and then evaporated to complete dryness. The solid product was purified by column chromatography on silica gel using chloroform:methanol (96:4) as eluent. Yield: 70 mg (62%).

UV–vis (dichloromethane) [$\lambda_{\text{max}}$, nm (ε, M$^{-1}$ cm$^{-1}$)]: 360 (3 × 10$^4$), 475(2 × 10$^4$), 574 (6 × 10$^3$), 620 (2.8 × 10$^3$).

**Synthesis of trans-2•ClO$_4$:**
To a dichloromethane (20 mL) solution of trans/cis-1 (100 mg, 0.079 mmol), a solution of 59 mg (0.167 mmol) Fe(ClO$_4$)$_3$ in 2 mL CH$_3$CN was added and the resulting solution was stirred in air at room temperature for 40 minutes. During the progress of the reaction, the colour of the reaction mixture changed from bright red to brown. The solution was then evaporated to complete dryness. The resulting solid was then dissolved in a minimum volume of CH$_2$Cl$_2$, filtered off to remove unreacted oxidant and then carefully layered with hexane. On standing for 8-10 days in air at room temperature, dark brown needle shaped crystals were obtained, which were then isolated by filtration, washed with hexane, and dried in vacuum. Yield 92 mg (70%).

UV–vis [$\lambda_{\text{max}}$, nm (ε, M$^{-1}$ cm$^{-1}$)]: 358 (1.2 × 10$^4$), 530 (1.0 × 10$^4$), 691 (0.6 × 10$^4$), 1150 (3.0 × 10$^3$).

**Synthesis of cis-3:**
To a dichloromethane (60 mL) solution of trans-2•ClO$_4$ (100 mg, 0.061 mmol), a solution of 1.5 ml of tetrabutylammonium hydroxide (25% in methanol) was added and the resulting solution was stirred in air at room temperature for 10 minutes. During the progress of the reaction, the colour of the reaction mixture changed from dark brown to dark green. The solution was then evaporated to complete dryness. The resulting solid was then dissolved in a minimum volume of CH$_2$Cl$_2$, and carefully layered with hexane. On standing for 6-8 days in air at room temperature,
dark green crystals were obtained, which were then isolated by filtration, washed with hexane, and dried in vacuum. Yield 48 mg (62%). UV-vis [$\lambda_{\text{max}}$, nm ($\epsilon$, M$^{-1}$ cm$^{-1}$)]: 367 (2.3 $\times$ 10$^4$), 417 (1.8 $\times$ 10$^4$), 471 (2.08 $\times$ 10$^4$), 569 (6.6 $\times$ 10$^3$).
