Experimental Section

**Synthesis of potassium perylene-3,4,9,10-tetracarboxylate (K\textsubscript{4}PTC):** Perylene-3,4,9,10-tetracarboxylic dianhydride (PTCDA) (3.92 g, 10 mmol, Aladdin Incorporation) was added into the deionized water (5 ml) with KOH (2.805 g, 50 mmol) at 55 \textdegree C. After stirring the mixture for 5 min, 35 ml deionized water was gradually added and sequentially stirred for another 12 h. Then, the solution was added to 300 ml EtOH and the yellow precipitate of K\textsubscript{4}PTC was formed with the yield above 80%. \textsuperscript{1}H-NMR spectra were recorded on AC Bruker spectrometer (400 MHz) at room temperature by using D\textsubscript{2}O as the solvent, and the chemical shifts were expressed in part per million (ppm) relative to the residual H\textsubscript{2}O. And the theoretical specific capacity of K\textsubscript{4}PTC is calculated to be 93 mAh g\textsuperscript{-1}.

**Preparation of K\textsubscript{4}PTC@CNT and K\textsubscript{4}PTC@SP compositions:** The K\textsubscript{4}PTC@CNT composite was simply \textit{in-situ} prepared as follows: 30 mg (5:60 weight relative to K\textsubscript{4}PTC) multi-walled carbon nanotubes (CNT) was uniformly dispersed in 100 ml N-methyl pyrrolidone (NMP)
under ultrasound for 30 min. And then 10 ml aqueous solution of K₄PTC (36 mg ml⁻¹) was added dropwise into the CNT solution under stirring. Finally the as-obtained precipitate was filtered and vacuum-dried at 110 °C overnight. The ball-milled sample of K₄PTC@SP was prepared in a planetary ball mill running at 400 rpm for 6 h by mixing K₄PTC with Super P (SP) with weight rate of 2:1 using 10 ml EtOH. The as-obtained sample was vacuum-dried at 110 °C overnight. The morphology images of the samples were collected by the field-emission scanning electron microscope (FE-SEM, Hitachi, S3400N).

**K-ion half cells fabrication and test:** The electrochemical measurements were carried out by using half cells of CR2023 type. The working electrode was prepared by casting the slurry onto a clear copper round disk (d=12 mm), where the slurry contains K₄PTC@CNT (65 wt%), carbon additive (acetylene black, 25 wt%) and poly(vinylidene fluoride) (PVDF, 10 wt%) or K₄PTC@SP (90 wt%) and PVDF (10 wt%). The loading of neat K₄PTC on copper foil was above 2 mg cm⁻². The as-prepared electrodes were dried in a vacuum oven at 110 °C for 12 h. The counter electrode was potassium foil and self-cut from potassium-metal block (Chengdu Kelong Inc.). The electrolyte was 1 M potassium bis(fluorosulfonyl)amide (KFSI, Ark Pharm Inc.) in the mixture solvents of ethylene carbonate (EC) and dimethyl carbonate (DMC) with the volume rate of 1:1 (Suzhou Fosai New Materials Co. Ltd.) and the water content was ~1 ppm in these solvents. The separate was glass microfiber filters (GF/F) of Whatman. These cells were assembled in the Ar-filled glove box with high purity of 99.9999%. The cyclic voltammetry (CV) test was operated by the BioLogic science instrument electrochemical workstation (VMP3-128). The galvanostatic charge-discharge curves were collected by a CT2001A cell test instrument (LAND Electronic Co.) during the voltage window of 0.1-2 V at room temperature. And the electrochemical impedance
spectroscopy (EIS) test was measured by a CHI instrument electrochemical workstation in the frequency range of $10^2$-$10^5$ Hz.

**Quantum calculations:** All the calculations were performed by Gaussian09 package at the level of density functional theory (DFT). K$_4$PTC and K$_6$PTC were optimized by the B3LYP functional, with the 6-31G* basis set. The solvent effect was with self consistent reactions field (SCRF) based on the SMD model, where the dielectric constant ($\varepsilon$) was set as 7.3 to mimic the experimental solvent condition. Frequency calculations at the same level were carried out to corroborate all of the stationary points as minima (no imaginary frequency) and to compute free energies at 298.15 K.
