Table of contents

I. Decomposition temperature of OdMI-TFSI in air (p2)
II. Determination of coagulation factor $\alpha$ (p3-4)
III. TG measurement of the vaporized EMI-TFSI (p5)
IV. Saturation vapour pressures of EMI-TFSI under various pressures (p6)
V. Deriving the empirical equation (5) displayed in the main article (p7)
VI. Clausius-Clapeyron plots of the tested ILs (p8)
Fig. S1 TG/DTA results of OdMI-TFSI in air. The decomposition temperature of OdMI-TFSI was not available in the other literature. The weight loss and exothermic onset temperature (562 K) was determined as the decomposition temperature of the IL. This value is listed in Table 1 of the main article. The endothermic peak around 320 K is due to the melting of OdMI-TFSI.
II. Determination of coagulation factor $\alpha$

According to the Hertz-Knudsen-Langmuir equation, the evaporation rate of liquid is expressed as:

$$ r = \alpha p \sqrt{\frac{M}{2\pi RT}} \quad (S1) $$

where $r$ is the evaporation rate, $\alpha$ is the coagulation factor ($0 < \alpha \leq 1$), $p$ is the saturation vapour pressure, $M$ is the molecular mass, $R$ is the gas constant, and $T$ is the absolute temperature. The coagulation factor means the hampering degree of evaporation by residual gas molecules. Under ultra-high vacuum, $\alpha$ may be regarded as 1; however, under low vacuum level or in air, $\alpha$ takes the value lower than 1, which causes the error of the saturation vapour pressure. Since the coagulation factor is an apparatus constant, we preliminarily determined the value.

According to the Clausius-Clapeyron equation, the external pressure and the boiling temperature are correlated as:

$$ \ln \frac{p_2}{p_1} = -\frac{\Delta H}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad (S2) $$

where $T_1$ and $T_2$ are boiling points under the external pressures of $p_1$ and $p_2$, and $\Delta H$ is the evaporation enthalpy. Once the boiling point in air ($1.01325 \times 10^5$ Pa) and the evaporation enthalpy are obtained, the boiling point under given external pressure can be calculated.

We selected eicosane ($\text{C}_{20}\text{H}_{42}$) as the standard compound with known boiling point in air (617.415 K) and evaporation enthalpy (101.8 kJ mol$^{-1}$). Using these data and equation (S2), the boiling points of eicosane under given external pressures can be calculated (334.1, 389.2, 411.6, 536.1 K under $5 \times 10^{-3}$, $9 \times 10^{-1}$, $5 \times 10^1$, and $5 \times 10^3$ Pa, respectively).

Next, we measured the TG data of eicosane under the above external pressures. The evaporation rates were then calculated from the following equation:

$$ r = -\frac{1}{U} \cdot \frac{d\Delta W}{dt} = -\frac{1}{U} \cdot \frac{d\Delta W}{dT} \cdot \frac{dT}{dt} \quad (S3) $$

Here, $U$ is the cross section area of the sample cell ($1.40 \times 10^{-5}$ m$^2$), $\Delta W$ is the weight loss, and $t$ is the time. The $dT/dt$ corresponds to the heating rate ($2 \degree C \cdot min^{-1}$). By applying the molecular weight of eicosane (282.5), the external pressure, and the evaporation rate and the estimated boiling point under the external pressure to equation (S1), $\alpha$ values could be obtained as summarized in Fig. S2 and Table S1.
**Fig. S2** The obtained coagulation factor versus the external pressure. The value asymptotically approach with 1 as the vacuum level increases.

**Table S1** The coagulation factors. Note that these values are apparatus constants of our setup.

III. TG measurement of the vaporized EMI-TFSI

**Fig. S3** Comparison of the TG data of pristine EMI-TFSI and once vaporized EMI-TFSI under $5 \times 10^{-3}$ Pa. The remeasurement was performed after collecting the deposited EMI-TFSI inside of the glass tube of the TG setup.
IV. Saturation vapour pressures of EMI-TFSI under various pressures

**Fig. S4** Saturation vapour pressure versus temperature obtained from the TG data and the Hertz-Knudsen-Langmuir equation under (a) $5 \times 10^{-3}$, (b) $5 \times 10^1$, and (c) $5 \times 10^3$ Pa, respectively.
V. Deriving the empirical equation (5) displayed in the main article

\[
\frac{T_{\text{onset}}}{T_{\text{onset}} + T_b} = -0.00681 \cdot \ln P_b + 0.444
\]

**Fig. S5** $T_{\text{onset}} / (T_{\text{onset}} + T_b)$ vs. $\ln P_b$ plot. $T_{\text{onset}}$ is the experimentally determined evaporation onset temperature of EMI-TFSI under each external pressure, $T_b$ is the estimated boiling point under each external pressure form the Clausius-Clapeyron plots, and $P_b$ is the external pressure. This equation could be applied to predict the evaporation onset temperatures of the other tested ILs (BMI-TFSI, HMI-TFSI, OdMI-TFSI, P13-TFSI, and Li-TFSI) within the error of about 4.6% as listed in Table 3 of the main article.
VI. Clausius-Clapeyron plots of the tested ILs

**Fig. S6** Clausius-Clapeyron plots of ILs. The enthalpy and the constant $C$ values are summarized in the main article.
