1. General Information

Unless otherwise noted, all reagents and solvents were obtained commercially and used without further purification. Column chromatography on silica gel (300-400 mesh) was carried out using technical grade 60-90 °C petroleum ether and analytical grade EtOAc (without further purification). $^1$H and $^{13}$C spectra were recorded on a 400 MHz or 500 MHz spectrometer. Chemical shifts were reported in ppm. $^1$H NMR spectra were referenced to CDCl$_3$ (7.26 ppm), and $^{13}$C-NMR spectra were referenced to CDCl$_3$ (77.0 ppm). Peak multiplicities were designated by the following abbreviations: s, singlet; d, doublet; t, triplet; m, multiplet; brs, broad singlet and J, coupling constant in Hz. HRMS spectra were recorded with Micromass QTOF2 Quadrupole/Time-of-Flight Tandem mass spectrometer using electron spray ionization. All devices of the electrolysis were purchased according to the Xu’s group (Ref. 9f-9i in the manuscript).
2. Studies on anti-tumor mechanism

2.1 Induction of cell cycle arrest

The cell cycle consists of two stages, namely, interphase and split phase (M phase). The M phase is further divided into three stages: genetic material DNA pre-synthesis stage (G1 stage), DNA synthesis period (S phase), and protein synthesis period (G2 stage), which is the late stage of DNA synthesis. Cell multiplication plays a vital role in tumor cell regeneration; as such, the compound that induces cell cycle arrest can inhibit cell proliferation. Our previous study indicated that compound 3ag could effectively inhibit the proliferation of T-24 cells, respectively. Therefore, flow cytometry analysis was conducted in the present work to investigate cell cycle distribution in T-24 cells treated with compound 3ag.

As shown in Fig. S1, upon exposure to compound 3ag, the percentage of T-24 cells in the G2/M phase increased from 7.52% to 27.40%; This finding indicated that compound 3ag significantly induced cell cycle arrest at the G2/M phase in T-24 cells.

**Figure S1.** Cell cycle distribution in T-24 cells treated with compound 3ag for 24 h.

2.2 Hoechst 33342 nucleic acid staining

Hoechst 33342 staining is a fluorescent dye that binds sturdily to nucleus and detect the nuclear damage or chromatin condensation. The hoechst 33342 stains the apoptotic cells as bright colored owing to the condensed nucleus which is a distinctive apoptotic characteristic. Hence, it was of our interest to detect nuclear damage or chromatin condensation persuaded by the compound 3ag in T-24 cells. Hoechst 33342 staining technique was performed according to earlier reported method. The results from Fig. S2 illustrated that the nuclear structure of untreated cells was intact whereas compound 3ag treated cells exhibited condensed, or fragmented nuclei.
Figure S2. Assessment of nuclear morphological changes by hoechst 33342 staining in T-24 cells after 24 h. Compound 3ag treated T-24 cells have displayed nuclear apoptotic characteristics such as nuclear fragmentation and shrunken nuclei.

2.3 Detection of released calcium ions

Ca$^{2+}$ as a death signaling molecule is involved in important life activities, such as cell shrinkage, movement, secretion, and division. When cells are stimulated by specific signals, calcium channels (mitochondria and endoplasmic reticulum) will be opened, resulting in a rapid increase in intracellular calcium concentration. Intracellular Ca$^{2+}$ levels were determined by fluorescence microscope with Fluo-3 AM staining kit, which could pass through the cell membrane and be cut into Fluo-3 by esterase. Fluo-3 could bind to the calcium ions to produce strong green fluorescence. As shown in Fig. S3, after treatment with compound 3ag (0 and 8 μM), the green fluorescence intensity increased significantly in T-24 cells. Hence, compound 3ag can increase the intracellular levels of Ca$^{2+}$. 
**Figure S3.** Changes in Ca²⁺ concentration in T-24 cells treated with compound 3ag determined with a Fluo-3AM staining kit under a fluorescence microscope. Scale bar: 100 μm.

### 2.4 Intracellular ROS

The DCFH-DA (2′,7′-dichlorofluorescein diacetate) probe was used to detect ROS content in cells. DCFH-DA cannot produce fluorescence but can freely pass through the cell membrane. Upon entry to the cell, DCFH-DA can be hydrolyzed by esterase into DCFH, which will not permeate the cell membrane but accumulate in the cell. ROS in the cells can oxidize the nonfluorescent DCFH to produce a green fluorescent DCF. The intensity of green fluorescence is proportional to the ROS level. Therefore, the green fluorescence intensity can reflect the concentration of ROS in cells.

As shown in Fig. S4, after treatment with compound 3ag (0 and 8 μM) for 24 h, the green fluorescence in T-24 cells were enhanced compared with that in the untreated controls. Hence, compound 3ag can increase the level of ROS in T-24 cells, respectively.

**Figure S4.** Changes in ROS concentration in T cells treated with compound 3ag determined with a DCFH-DA staining kit under a fluorescence microscope. Scale bar: 100 μm.

### 2.5 Inhibition of polymerization of microfilaments

T-24 cells were treated with compound 3ag (0 and 8 μM) for 24 h and stained with hoechst 33342 and anti-β-tubulin antibody (EPR16774, ab179513). As shown in Fig. S3, cells in the control group exhibited normal filamentous microtubules arrays.
However, after treatment with compound 3ag, the cells showed reduced microtubule networks, indicating the decreased expression of the microtubule protein. Hence, compound 3ag can inhibit the polymerization of microtubules and disrupt their organization (Fig. S5). The result indicated that compound 3ag induced the collapse of the microtubule network and interfered with the mitosis of T-24 cells.

**Figure S5.** Fluorescence microscopic (Cytation 5 Cell Imaging Multi-Mode Reader, BioTek Instruments, Inc., USA) images of T-24 cells stained with hoechst 33342 and anti-β-tubulin antibody after treatment with compound 3ag 24 h.

### 2.6 Wound healing assay

Metastasis is a multistep process involving cancer cell motility and invasion which accounts for more than 90% of cancer related deaths. Microtubule or tubulin network plays an important role in cell motility and migration. As the compound 3ag inhibits tubulin polymerization, we have investigated their migration inhibition capacity through wound healing assay. In this assay, standardized scratches (wounds) were made in confluent monolayers of T-24 cells and incubated with increasing concentrations of the compound 3ag (0, 4 and 8 μM). The number of cells migrated into the wound area were captured using phase contrast microscope after 0 and 24 h incubation. As shown in Fig. S6, the compound 3ag treatment resulted in significant inhibition of migration capacity of T-24 cells and the effect was more prominent after 24 h. For instance, compound 3ag treatment at 4 and 8 μM concentration led to strong inhibition of migration in to the scratch area in relative comparison to control after 24 h. It can be inferred from the results that the compound 3ag suppresses the migration potential of the T-24 cells in dose dependent manner.
Figure S6. Effect of compound 3ag on in vitro migration potential of T-24 prostate cancer cells. Scratches were created with sterile 200 μL pipette and images were captured using fluorescence microscopic (Cytation 5 Cell Imaging Multi-Mode Reader, BioTek Instruments, Inc., USA) at 0 h and 24 h after treatment with 0, 4 and 8 μM of compound 3ag.

3. Experimental Section

3.1 Synthesis of unsymmetrical thiosulfonates

\[
\text{(Het)Ar} \quad \text{S} \quad \text{NHNH}_2 \quad + \quad \text{HS-R} \quad \xrightarrow{\text{RVC, } \text{Pt}, \text{NH}_4 \text{I (10 mol %)}} \quad \text{(Het)Ar} \quad \text{S} \quad \text{S-R}
\]

The sulfonyl hydrazides (0.3 mmol, 1.0 equiv), thiols (0.3 mmol, 1.0 equiv) and NH₄I (0.03 mmol, 0.01 equiv) were placed in a 10 mL three-necked round-bottomed flask. The flask was equipped with a condenser, a RVC (100 PPI, 1 cm x 1 cm x 1.2 cm) anode and a platinum plate (1 cm x 1 cm) cathode. MeCN (6.0 mL) were added. The electrolysis was carried out at room temperature using a constant current of 10 mA until complete consumption of the substrate (monitored by TLC, about 3 h). The reaction mixture was concentrated and the residue was chromatographed through silica gel eluting with ethyl acetate/petroleum ether to give the products.

3.2 Anticancer activity assay

The 180 μL cell suspensions (4500-5000 cells/mL) was seeded in 96-well plates and
incubated for 24 h. All compounds and 5-FU were dissolved in the Phosphate Buffered Saline (PBS) with 1% DMSO to give various concentrations (2.5, 5, 10, 20, and 40 μM, respectively) to 96-well plates and control wells contained supplemented media with 1% DMSO. Continue incubating for 48 h at 37 °C in 5% CO₂ atmosphere and then the MTT solution (10 μL, 5 mg/mL) was added into each well and the cultures were incubated further for 4–6 h. After removal of the supernatant, DMSO (100 μL) was added to dissolve the formazan crystals. The absorbance was read by enzyme labeling instrument with 570/630 nm double wavelength measurement. The cytotoxicity was estimated based on the percentage cell survival in a dose dependent manner relative to the negative control. The final IC₅₀ (a drug concentration killing 50% cells) values were calculated by the Bliss method. All the tests were repeated in at least three independent experiments.

3.3 Cell cycle analysis

T-24 cells were treated with different concentrations of compound 3ag (0, 8, and 12 μM). After incubating for 24 h. The cells were collected and used PBS washed twice, fixed with 9 ml 70% ice-ethanol at -20 °C overnight. The ethanol was removed and replaced with the 0.5 mL RnaseA (10 mg/ml, Sigma) for 30 min at 37 °C, then added 20 μL PI (1 mg/mL, Sigma) for 15 min in dark. Flow cytometry (FACScan, Becton Dickinson, San Jose, CA) was used to analyze the cell cycle distribution.

3.4 Hoechst 33342 nucleic acid staining

Nuclear morphological changes were observed through hoechst 33342 staining. After treatment with compound 3ag for 24 h in T-24 cells, cells were washed with PBS and permeabilized with 0.1% Tween 20 for 10 min followed by staining with hoechst 33342 (2.5 μg/mL). Control and treated cells were observed with fluorescence microscope (Cytation 5 Cell Imaging Multi-Mode Reader, BioTek Instruments, Inc., USA.).

3.5 Measurement of intracellular reactive oxygen species

Intracellular reactive oxygen species (ROS) was detected by using fluorescence microscope by with 2′,7′-dichlorofluorescein diacetate (DCHF-DA) staining kit. T-24 cells were seeded at 2×10⁶/well in 10% FBS/DMEM into 6-well plates and treated with different concentrations of compound 3ag (0 and 8 μM) for 24 h, then cells were washed twice with serum free DMEM and
incubated with DCHF-DA for 30 minutes at 37 °C in dark. The fluorescence microscope was used to measure the enhanced green fluorescent intensity in cells, the intensity of the microscope is 488 nm, and the emission wavelength is 525 nm.

3.6 Measurement of intracellular Ca²⁺ levels

The intracellular Ca²⁺ levels were determined by fluorescent with Fluo-3 AM staining kit, which could pass through the cell membrane and be cut into Fluo-3 by the esterase. The Fluo-3 could bind with calcium ions to produce strong green fluorescence. T-24 cells were seeded at 2×10⁶/well in 10% FBS/DMEM into 6-well plates and incubation for 24 hours. After the cells were treated with compound 3ag (0 and 8 μM) for 24 h, the Fluo-3 AM (5.0 μ M) was added and incubated for 30 min at 37 °C. The fluorescence microscope was used to measure the enhanced green fluorescent intensity in cells, the intensity of the microscope is 506 nm, and the emission wavelength is 526 nm.

3.7 Tubulin polymerization assay

The effects of compound 3ag on tubulin were detected using an anti-beta tubulin antibody (EPR16774, ab179513). The T-24 cells were seeded in 6-well plates (2×10⁶ cells/well ) and cultured for 24 h. After treated with compound 3ag (0 and 8 μM) for 24 h, the cells were fixed with 4% paraformaldehyde for 10min, and were permeabilized with 0.1% Triton X-100 for 10min. Then incubation with tubulin proteins (1/1000) at 4 °C overnight. Followed by anti-rabbit Alexa Fluor 488 secondary antibody at 1/5000. Confocal image showing cytoplasmic staining on T-24 cells. The nuclears were stained by hoechst 33342 (2.5 μg/mL) for 30 min. Fluorescence microscope was used to observed the change of microtubule networks in cells.

3.8 Wound healing assay

T-24 cells (5×10⁵ cells/well) were grown in petridishes for 24 h. Scratches were made in confluent monolayers using 200 m L pipette tip. Then, wounds were washed twice with PBS to remove non-adherent cell debris. The media containing different concentrations (0, 4 and 8 μM) of the compound 3ag wereadded to the petridishes. Cells which migrated across the wound area were photographed under the fluorescence microscope (Cytation 5 Cell Imaging Multi-Mode Reader, BioTek Instruments, Inc., USA) after 0 and 24 h treatment.
