Supporting Information

Experimental

Materials.

Co(NO\textsubscript{3})\textsubscript{2}\cdot6H\textsubscript{2}O, thioacetamide (TAA), sublimed sulfur, glycerol, isopropanol and ethanol were purchased from Sinopharm Chemical Reagent Co., Ltd. (China). All the chemical reagents used here were analytical grade without further purification.

Synthesis of double-shelled hollow Co\textsubscript{9}S\textsubscript{8} nanospheres and Co\textsubscript{9}S\textsubscript{8}@CNTs composites.

Double-shelled Co\textsubscript{9}S\textsubscript{8} nanospheres were prepared according to the literature with some modifications.\textsuperscript{1} In a typical process, 109 mg Co(NO\textsubscript{3})\textsubscript{2}\cdot6H\textsubscript{2}O and 8 ml glycerol were dissolved in 40 ml isopropanol. After 20 min stirring, the transparent pink solution was then sealed in a Teflon-lined stainless-steel autoclave and heated at 180 °C for 6 h. As the autoclave cooled down to room temperature, the light pink precipitate was collected by centrifugation and washed with ethanol several times. After dried in the oven at 60 °C, 30 mg of the obtained precursor Co-glycerate spheres and 75 mg TAA were added into 20 mL ethanol, stirred for 2 h and transferred into Teflon-lined stainless-steel autoclave. After heating at 160 °C for 6 h, the black product was obtained by centrifugation, washed with ethanol several times and finally dried in the vacuum oven at 60 °C. For the preparation of double-shelled Co\textsubscript{9}S\textsubscript{8} nanospheres, the as-prepared samples were annealed at 800 °C under the Ar atmosphere for 6 h. For the preparation of Co\textsubscript{9}S\textsubscript{8}@CNTs composites, the as-prepared samples were annealed at 800 °C under the continuous acetylene/argon gas flow (1/9) for 6 h.
Synthesis of Co$_9$S$_8$@CNTs/S composites.

Sublimed sulfur and double-shelled Co$_9$S$_8$@CNTs nanospheres were dispersed in the mixed solution of 10 mL ethanol and 10 mL carbon disulfide and stirred until the solution was evaporated. The sample was put into the oven at 60 °C to remove the remaining ethanol and carbon disulfide. Then the obtained dried sample was hand-milled and sealed in a quartz tube at 155 °C for 10 h. Upon cooling down, the Co$_9$S$_8$@CNTs/S composites were prepared.

Structure characterizations.

The morphologies of the samples were characterized by scanning electron microscopy (SEM) (Carl Zeiss Supra 40 field emission scanning electron microscope); transmission electron microscopy (TEM) images were taken on a field emission Hitachi H7650 transmission electron microscope. The high angle annular dark-field scanning TEM (HAADF-STEM) energy-dispersive x-ray spectroscopy (EDS) element mappings and line scans were carried out with a JEOL ARM-200F transmission electron microscope. Powder X-ray diffractometer (XRD) was performed on the Philips X’pert Super diffractometer with Cu Kα radiation ($\lambda=1.54178$ Å). Thermogravimetric analysis (TGA) was conducted to evaluate the content of sulfur in the composites. The Brunauer-Emmett-Teller (BET) surface area and Barrett-Joyner-Halenda (BJH) pore distribution plots were measured on an ASAP 2020 accelerated surface area and porosimetry instrument. The pore size distribution was calculated from the adsorption branch of the isotherms using the non-local density functional theory.

The preparation of Li$_2$S$_6$ and the adsorption test.
0.2 M Li$_2$S$_6$ was prepared as follows: 2 mmol Li$_2$S and 10 mmol S was dissolved in 10 mL 1 M LiTFSI in the mixture of 1,3-dioxolane (DOL) and dimethoxymethane (DME) (1:1, v/v). 20 μL of 0.1 M Li$_2$S$_6$ solution was dropwise added into 1 mL tetrahydrofuran (THF) in a glass vial and then 5 mg different samples (CNT, Co$_9$S$_8$ and Co$_9$S$_8$@CNTs) was added into three vials, respectively. Finally, the adsorption capability was evaluated by comparing the color change of the solution.

**Electrochemical Measurements.**

The electrochemical performance was measured in the 2016-type coin cells, which were assembled in the argon-filled glove box (H$_2$O, O$_2$ < 1 ppm). For the symmetric electrochemical studies, the obtained sample (Co$_9$S$_8$@CNTs, Co$_9$S$_8$ or CNTs) and poly(vinylidene fluoride) binder were mixed in the N-methyl pyrrolidone with a weight ratio of 8:2, then dispersed onto the Al foil and dried at 110 °C for 12 h. The prepared electrodes with the same loading amount were assembled into a symmetric electrochemical cell with 0.2 M Li$_2$S$_6$ as the electrolyte. The electrodes for general Li-S battery studies were prepared by mixing the as-prepared composites, Ketjen Black and poly(vinylidene fluoride) binder in N-methyl pyrrolidone with a weight ratio of 7:2:1. The slurries were then pasted onto an Al foil and dried at 70 °C in the vacuum oven for 12 h. The obtained Al foil was cut into circular pieces with a diameter of 12 mm as the electrodes. Unless otherwise noted, the loading of sulfur in each electrode is about 1 mg cm$^{-2}$. The lithium foils were used as the counter electrode, celgard 2400 as the separator. The electrolyte was 1 M lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) in a mixture of 1,3-dioxolane (DOL) and dimethoxymethane (DME) (1:1, v/v) with 1% LiNO$_3$. Cycling voltammograms (CV) and electrochemical impedance spectroscopy
(EIS) were measured on the electrochemical workstation CHI 660e. Galvanostatic measurements were performed on the LANDCT2001A instrument at room temperature with different rates. The galvanostatic intermittent titration technique (GITT) was conducted at the current density of 0.1 C for 0.5 h with the following rest for 3 h. The reaction resistant was evaluated via the difference in the potential of the end of current step and the end of the relaxation step. The visual tests of the polysulfides shuttling was performed in a sealed transparent bottle with the same electrolyte as the coin cell at the rate of 0.05 C.

**Computational methods.**

All calculations were performed using the plane-wave-based periodic DFT method in the CASTEP software as implemented in the Materials Studios package of Accelrys Inc. The electron exchange-correlation potential was treated by the Perdew-Burke-Ernzerhof (PBE) functional of generalized gradient approximation (GGA) and the DFT dispersion correction (DFT-D) method was used to treat the van der Waals interactions. The ultrasoft pseudopotentials was employed and the core electrons of atoms were treated using effective core potential (ECP). The energy cutoff was set to 400 eV for the plane-wave basis set with the Brillouin zone integration sampled with the $4 \times 4 \times 4$ and $2 \times 3 \times 1$ Monkhorst-Pack mesh k-point for bulk and surface calculations. Based on the corresponding optimized bulk unit cell, which is in good agreement with the experimental values, the $\text{Co}_{10}\text{S}_8$ terminated $\text{Co}_9\text{S}_8$ (1 1 0) surface was created by a periodic four-layer slab repeated in $1 \times 1$ surface unit cell with a vacuum region of 10 Å between the slabs along the Z axis, where the adsorbates together with four layers of surfaces atoms were all relaxed during the geometry optimizations. The convergence tolerances are set to 5.0 *
10^{-6} \text{ eV per atom for energy, } 5.0 \times 10^{-4} \text{ Å for maximum displacement, and } 0.01 \text{ eV Å}^{-1} \text{ for maximum force. The adsorption energy of Li}_2\text{S}_6 \text{ on the surface was defined as } E = E_{\text{Surface+Li}_2\text{S}_6} - E_{\text{Li}_2\text{S}_6} - E_{\text{Surface}}, \text{ where } E_{\text{Surface+Li}_2\text{S}_6} \text{ is the total energy of the adsorbed system, } E_{\text{Li}_2\text{S}_6} \text{ is the energy of isolated Li}_2\text{S}_6, \text{ and } E_{\text{Surface}} \text{ is the energy of the optimized clean surface slab.}

Supplemental note: The optimization of the loading of Co$_9$S$_8$

We have studied the effects of Co$_9$S$_8$ loading weights on the electrochemical properties. The weight content of Co$_9$S$_8$ was tuned from 18.45 to 41.6 wt % by changing the CNT growth time in Ar/C$_2$H$_2$ atmosphere (Fig. S7). The electrochemical performance evaluated in the symmetrical cell, as shown in the Fig. S8a, S8b displays the sample with Co$_9$S$_8$ contents of 20.2 wt % exhibits lowest potential polarization and largest current density. Moreover, the Li-S battery performance measured in the 2016-type coin cells also reveals the sample with Co$_9$S$_8$ contents of 20.2 wt % has the best cycling stability and specific capacity (Fig. S8c). Taken together, the optimal loading of Co$_9$S$_8$ is ~20%. Increasing or reducing the loading amounts will affect the synergistic balance between of Co$_9$S$_8$ and CNTs on the interfacial electrical conductivity and polysulfide redox kinetics, and thus affect their electrochemical performances.
