Monitoring the growth of Ag NPs by LSPR spectra

Figure S1 LSPR spectra of GND-supported Ag NPs as a function of precursor AgNO$_3$ concentration (a) and irradiation time (b). The intensity of LSPR peak increases but show little shift with the irradiation time, indicating the increasing number of Ag NPs during photoreduction, instead of particle size.
The effect of GND template on the loaded Ag NPs

Figure S2 (a) The TEM size histogram of GND-Ag NPs. GNDs are synthesized by using carbon fiber (black) and GO (red) as starting materials. The mean values and standard deviations are shown inset. (b) LSPR spectra of GND-Ag NP solution. GND types: carbon fiber based (red); GO (cyan) based.
Estimation of surface density of deposited GND-Ag NPs

A direct method for calculating the surface concentration, \( \Gamma \) (particles\( \cdot \)cm\(^{-2} \)), is to measure the number of GND-Ag NPs (\( N \)) present on a quartz substrate of known surface area (\( SA \)). We assume the GND-Ag NPs form a tightly packed well-ordered monolayer on quartz substrate, and then the surface density is defined as:

\[
\Gamma (\text{particles} \cdot \text{cm}^{-2}) = \frac{N(\text{particles})}{SA(cm^2)}
\]  

(1)

with the substrate surface area, \( SA \), equal to 4.909 cm\(^2\) (2.5 cm diameter quartz). In addition, the measurable mass of deposited GNDs-Ag NPs, is considered as the product of the mass of single particle, \( m_0 \), and the particle numbers, \( N \):

\[
m = N \cdot m_0
\]  

(2)

The GNDs-Ag nanoparticle is briefly treated as quasi-sphere with a radius (\( r_{Ag} \)) of 1.6 nm and specific gravity (\( \rho_{Ag} \)) of 10.5 g\( \cdot \)cm\(^{-3} \). Then the eq(2) can be written as:

\[
m = N \cdot \rho_{Ag} \cdot \frac{4}{3} \pi r_{Ag}^3 = \gamma_i \cdot V
\]  

(3)

where \( \gamma_i \) is the mass concentration and the \( V \) is the pipetted volume of the GND-Ag NP solution. During the casting process, the \( \gamma_i \) in the range of 4-50 µg\( \cdot \)mL\(^{-1} \), and the \( V \) is 300 µL. Finally, the surface density can be determined as:

\[
\Gamma (\text{particles} \cdot \text{nm}^{-2}) = 8.893 \times 10^{10} \gamma_i
\]  

(4)

**Figure S3** The AFM images of GND-Ag NPs on quartz when casting from increasing concentration of solution. (a) 4 µg/mL; (b) 8 µg/mL; (c) 12 µg/mL; (d) 50 µg/mL.
PL quenching of GNDs by the loaded Ag NPs

Figure S4 PL spectra of the GNDs and AgNO$_3$ mixture at increasing irradiating time, indicating the growing Ag loadings induce increasing PL quenching of the GNDs. The concentrations of GNDs and AgNO$_3$ solution are 0.1 mg/mL and 1 mg/mL, respectively. 254 nm UV lamp (8 W) was adopted.
Morphologies of spun CP films

Figure S5 AFM images of the surface morphologies of spun CP films on quartz. (a) F8BT; (b) PFO; (c) MEH-PPV.
Figure S6 Steady PL spectra of CP films spun on top of GND-Ag NP monolayer with various surface densities of GND-Ag NPs, $\Gamma_{\text{GND-Ag}}$, (a) PFO, $\lambda_{\text{ex}} = 350$ nm; (b) F8BT, $\lambda_{\text{ex}} = 420$ nm; (c) MEH-PPV, $\lambda_{\text{ex}} = 420$ nm.
Figure S7 Transient PL decay curves of CP films spun on top of GND-Ag NP monolayer with various surface densities of GND-Ag NPs, $\Gamma_{\text{GND-Ag}}$ (a) PFO, $\lambda_{\text{em}} = 450$ nm; (b) F8BT, $\lambda_{\text{em}} = 550$ nm; (c) MEH-PPV, $\lambda_{\text{em}} = 600$ nm.
CP film thickness dependence of the PL lifetime

Figure S8 (a-c) AFM images of the surface morphologies of spun F8BT films with various thickness, \( h \). (a) 2 nm; (b) 23 nm; (c) 36 nm. (d) Transient PL decay curves of F8BT films with various thicknesses. (e) PL lifetime of F8BT films as a function of film thickness.

\(^a\)The quenching distance corresponds to the Förster radius (\(R_0\)) calculated from FRET theory when the non-metal quencher is used, while corresponds to the characteristic distance \(d_0\) calculated from PRET theory using GND-Ag NPs as quencher in this work.
Measurements of $(\text{PDDA/PSS})_n/\text{PDDA}$ spacer thickness

**Figure S9** Absorption spectra of assembled $(\text{PDDA/PSS})_n/\text{PDDA}$ layer with the integer $n = 0$ to 8. Inset shows the optical density as a function of the number of PDDA/PSS layer monitored at 225 nm.
Figure S10 The thickness of \((\text{PDDA}/\text{PSS})_n/\text{PDDA}\) layer with the \(n = 0\) to 8 was measured using an AFM. The film was scratched with a wood stick and the step height along several scratches was measured. AFM images of scratch layer border with \(n = 4\) (a) and 7 (b) show above. (c) The measured thickness of self-assembled film as a function of number of layers. The red line represents the linear fit equation \(y = 0.99x\), indicating a self-assembled layer is about 1 nm.
Absorption spectra of the bilayer structure

Figure S11 Absorption spectra of the bilayer structure of GND-Ag NPs/[(PDDA/PSS)$_n$/PDDA]/F8BT with the integer $n = 0$ to 6, where the $\Gamma$-value was set to be $4.4 \times 10^{-2}$ nm$^{-2}$ and the $h_{cp}$ was 2 nm.
Spacer thickness dependent transient PL spectra

Figure S12 Transient PL decay curves of the bilayer structure of GND-Ag NPs/[(PDDA/PSS)_n/PDDA]/F8BT with the spacer thickness ranging from 0 to 6 nm, where the Γ-value was set to be $4.4 \times 10^{-2}$ nm$^{-2}$ and the $h$ was 2 nm.
Photoelectrochemical study

**Figure S13** Photocurrent density versus time curves of F8BT films on ITO (black) and GND-Ag NPs (blue) photoanodes in sat. KCl as reference electrode, Pt wire as counter electrode and the prepared films with an active area ca. 0.12 cm² as working electrode. Light source: 300 W Xe lamp (100 mW·cm⁻²); Scanning rate: 20 mV·s⁻¹.
