1 Material and methods

Experimental procedures

Unless otherwise indicated, reactions were carried out under an argon atmosphere in flame-dried glassware with magnetic stirring. Air and/or moisture-sensitive liquids were transferred via syringe. When required, solutions were degassed by argon bubbling through a needle. Organic solutions were concentrated by rotary evaporation at 25-80 °C at 15-30 torr. Analytical thin layer chromatography (TLC) was performed using plates cut from aluminium sheets (ALUGRAM Xtra SIL G/UV$_{254}$ from Macherey-Nagel). Visualization was achieved under a 254 or 365 nm UV light and by immersion in an appropriate revelation solution.

Materials.

All reagents were obtained from commercial sources and used without any further purifications. Anhydrous solvents used in experiments were obtained from Sigma-Aldrich or Alfa Aesar. Pd/C was purchased from Alfa Aesar (A12012 Palladium, 10% on carbon, Type 487, dry). Silica gel for column chromatography was purchased from Merck (Geduran® Si 60, 40-63 μm). Column flash chromatography was carried out using silica gel G-25 (40-63 μm) from Macherey-Nagel.

Instrumentation

NMR spectroscopy, $^1$H and $^{13}$C NMR spectra were recorded respectively at 400 MHz and 100 MHz with a Bruker 400 spectrometer at 23 °C. Data are represented as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, quint = quintet, m = multiplet, br = broad or a combination of the above), coupling constant (J, Hz) and integration.

High resolution mass spectra (HRMS) were obtained using an Agilent Accurate Mass QToF 6520 (PACSI Platform, Strasbourg University).

Semi-Preparative HPLC: The semi-preparative HPLC system consisted of a Waters 600 pump, a 2487 detector (Waters), a 5 mL sample loop. Column: Sunfire C$_{18}$ (150 mm × 19 mm i.d., 5 μm, Waters). Flow: 17 mL/min. Injection volume = 1 mL. Eluent A/B water/ACN, with 0.05% TFA. Gradient: 5% B to 95% B in 40 minutes and 10 minutes of re-equilibration. Detection: 254 nm.

3 Reductive azide dimerization

3.1 Optimization of reductive azide dimerization

The optimization of the reductive azide dimerization step was then performed using the heterobifunctional OEG₄ 4a as model substrate. We screened several parameters, including the catalyst loading, the reactant concentration, the temperature and the solvent, and compared by ¹H-NMR spectroscopy the ratio between the expected dimer 8a and the amine side-product 7a resulting from the simple reduction. The ¹H-NMR ratios were determined by integrating the peaks corresponding to the protons located in the alpha position of the amine group (2 ¹H for compound 7a and 4 ¹H for compound 8a, Figure 1). The results are summarized in Table 1.

Figure 1: Determination of dimer 8a and amine side-product 7a ¹H NMR ratio. a. Amine side-product 7a ¹H NMR. b. Expected dimer 8a ¹H NMR. c. Dimerization crude ¹H NMR, [azide 4a] = 500 mM in EtOH, Pd/C 5% mol. (Table 1, entry 7).
