6. Material and methods

General: All the chemicals, reagents and solvents were procured from local companies (Sigma-Aldrich, Loba chemi, Merck, S D Fine) and used without further purification. The high quality solvents were used after drying by means of standard procedures. In the chromatographic separations, silica gel (100-200 and 230-400 mesh, Merck made) or neutral aluminium oxide (Merck made) was used as stationary phase. Aluminium sheets coated with silica gel were used for thin layer chromatography (TLC) to monitor the reactions and column purifications. FTIR spectra were measured on Bruker alpha Fourier Transform IR spectrophotometer using ATR method at room temperature and only major peaks are reported in cm$^{-1}$. $^1$H NMR were recorded on Bruker machine at 500 MHz and $^{13}$C NMR at 125 MHz using CDCl$_3$ solvent (Sigma-Aldrich made) and chemical shifts were reported in $\delta$ related to TMS internal standard. Elemental analysis was performed on a Carlo-Erba Flash 1112 analyser. Mass spectrometric analysis was carried out using MALDI-TOF mass spectrometer.

The optical textures of mesogenic materials were acquired by employing Olympus BX51 Polarized Optical Microscope (POM) connected with a Mettler FP82HT hot stage and FP90 central processor attached with a digital camera (Olympus, Tokyo, Japan). DSC traces were obtained on METTLER TOLEDO DSC 3 STAR$^e$ system with PC system operating on STAR$^e$ software. Prior to the use, the instrument was calibrated using pure indium and zinc. All thermograms were recorded at a scan rate of 5 °C min$^{-1}$ under a continuous flow of nitrogen gas. The temperature dependent X-ray diffraction (XRD) measurements were performed on unoriented samples filled in a Lindemann capillary of the diameter of 1 mm (Hampton Research) with Cu $K_a$ ($\lambda = 1.54060$ Å) radiation using DY 1042-Empyrean X-ray diffractometer comprising a programmable divergence slit and PIXcel 3D detector.

The steady-state UV-visible and fluorescence spectra were recorded using SPECORD S 600 UV-visible spectrophotometer and Fluoromax 4 HORIBA spectrofluorometer, respectively. Absolute quantum yields were determined by using an integrated sphere set-up EDINBURGH (UK) and FLS 980 TCSPC instrument. Fluorescence life time was estimated by employing the Time-Correlated Single Photon Counting (TCSPC) technique using a nano-LED with a spectral width of 1.2 nm as an excitation source and their decay profiles were best fitted using DAS6 software. Electrochemical properties of LC materials were studied by using CH-instrument connected to CHI660E software. The CV experiments were carried out by
employing Ag/AgCl as a reference electrode, calibrated with ferrocene/ferrocenium (Fc/Fc⁺) redox couple which has the absolute energy 4.8 eV to vacuum, glassy carbon as a working electrode, platinum wire as a counter electrode, tetrabutyl ammonium perchlorate (0.1 M) as the supporting electrolyte in dry dichloromethane solvent.

**Device Fabrication and Measurement:**

The OLED devices were fabricated using patterned indium tin oxide (ITO, Kintec, Hong Kong) coated glass substrates with a sheet resistance of 15 Ω square⁻¹ and ITO thickness of 120 nm were used as transparent anodes. Prior to the deposition of organic materials, the ITO substrates were treated by the UV-Ozone after a careful series of chemical cleaning process. All the organic and cathode materials were purchased from Sigma-Aldrich and used as received without further purification. A hole injection material poly(3,4-ethylenedioxythiophene)/poly(styrene-sulfonate) (PEDOT: PSS) was spin-coated on the ITO substrates of 50 nm thick from aqueous dispersion and baked at 120 °C for 30 min. Then, Py-2 (device I) or a mixture of CPO-2 (10 wt.%) and the Poly(9-vinylcarbazole) (PVK) host (device II/III) was spin-coated onto the hole injection layer. The thickness of emissive layer was controlled as 80 nm by adjusting the solution concentration and the spin rate. After coating the emission layer, the substrates was annealed at 135 °C for 2 hrs and slowly cooled at a rate of 1 °C/min. In the device II, PVK was also used as a hole transport material. The substrates were then transferred into a deposition chamber to deposit the remaining layers with a base pressure of 10⁻⁵ torr. In case of device III, Bathocuproine (BCP, Sigma Aldrich) as the hole blocking material and tris-(8-hydroxyquinoline)aluminum (Alq₃, Sigma Aldrich) as the electron transport material were deposited in sequences and thicknesses appropriate for the device structure by thermal evaporation. Finally, to improve electron injection, a bilayer cathode consisting of lithium fluoride (LiF, Sigma Aldrich) and aluminium (Al, Alfa Aesar) layers were sequentially deposited on the electron transporting material as a cathode. Here, LiF works as electron injecting material. All organic materials and cathode layers were deposited by thermal evaporation at a chamber pressure of 5 x 10⁻⁶ Torr. The deposition rates of LiF and Al layers were maintained at 0.5 Å s⁻¹, 0.1 Å s⁻¹ and 6 Å s⁻¹, respectively. The cathode was deposited on the top of the structure through a shadow mask. The light-emitting area was 1.6 mm² as defined by the overlap of the cathode and anode. Electroluminescence spectra was acquired using a Horiba Jobin Yvon iHR320 spectrophotometer with an attached charge-coupled device (CCD) camera. The opt-electrical characteristics were recorded in a customized setup using a computer-controlled programmable Keithley 2400 SMU for recording the current-voltage
characteristics while the luminance was measured by a Keithley 6485 picoammeter using a calibrated Si photodiode (SM1PD2A). CIE coordinates were calculated from the EL spectra. Devices were driven under DC conditions. All the measurements were carried out at room temperature under dark and ambient conditions without any encapsulation.
