Experimental

The photocatalytic activity of Cu$_2$O/TNTs for the phenol photodegradation under visible light can be described as follows:

Initially, 120 mL of phenol solution with an initial concentration of $6.25 \times 10^{-5}$ (mol.L$^{-1}$) and 0.04 g of catalyst were stirred magnetically for 60 min to reach the adsorption/desorption equilibrium in the dark. Secondly, the mixture was then irradiated to a simulated Xenon lamp (ABET 230 V, 150 W). The visible light was separated by an UV-cut optical filter ($\lambda > 420$ nm). The absorption spectra of phenol was recorded at regular intervals (30 min) of irradiation. The photocatalytic efficiency ($\eta$) was calculated by using the following formula,

$$\eta[\%] = \frac{C_0 - C_t}{C_0} \times 100,$$

where $C_0$ and $C_t$ is the absorption intensity of the phenol solution at 270 nm of wavelength after the adsorption/desorption reached on the equilibrium and at time $t$, respectively. The stability of the photocatalytic activity of Cu$_2$O/TNTs was tested by the measurement of the recycle for 5 times.

The evaluated oxygen contents of TNTs and Cu_2O/TNTs were determined based on the XPS results of O 1s, Ti 2p, and Cu 2p respectively. The estimated results tabulated in Table S1 show that the percentage of oxygen vacancies increased after the formation of the heterojunction structure of Cu_2O and TNTs leading to the increase of the surface hydroxyl oxygen.¹

Figure S1. Phenol photodegradation ability of the TNTs and Cu_2O/TNTs under visible light

Moreover, phenol solution is well known as a hard remediation and no self-sensitization by visible light.² Therefore, phenol is widely used as an organic pollutant indicator. Figure S1 shows the phenol photodegradation over TNTs and Cu_2O/TNTs for 150 min under visible
light. The result shows that the TNTs have low photocatalytic performance in this case due to its large band gap and poor photoactive ability in visible light. Meanwhile, it is clear that, the Cu$_2$O/TNTs heterojunction is much more active, which confirms that the formation of heterojunction can strongly enhance the visible-light activity of the TNT. Generally, the stability Cu$_2$O semiconductor is poor; however, the Cu$_2$O/TNTs heterojunction exhibits good stability after 5 times of recycling test, as shown in Figure S2.

![Figure S2. Photocatalytic stability of Cu$_2$O/TNTs](image)

Additionally, the structural stability of Cu$_2$O was further tested by annealing it in hydrogen environment in the temperature of 150 °C and 300 °C. The experiment was conducted in a quartz tube with 5sccm of hydrogen flow rate for 2 hours. Initially, the Cu$_2$O/TNTs has a light yellow color (Figure S3 (b)) which then slightly change upon the reduction by hydrogen at 150 °C, as shown in Figure S3 (c). The color of the powder was changed to black at 300 °C (Figure S3 (d)). This result indicates the presence of CuO.³
Moreover, Figure S4 shows that the BE peaks of Cu 2\textit{p}_{1/2} and Cu 2\textit{p}_{3/2} for the sample annealed at 150 °C in hydrogen are similar to those of as-prepared sample. Both position and the separation between the peaks unchanged. However, the same two peaks for the sample annealed at 300 °C in hydrogen gas strongly undergo a blue shift. The position of Cu 2\textit{p}_{1/2} and Cu 2\textit{p}_{3/2} peaks for the sample annealed at 300 °C appeared at 952.7 eV and 933.2 eV, respectively. This observation indicates the presence of Cu\textsuperscript{2+} state in the sample.\textsuperscript{4-6} These HRXPS results are well consistent with the result of the color change of samples in the Figure S3. In conclusion, although hyrogen gas has a high reductive property but the Cu\textsubscript{2}O/TNTs still remain the stable ability in this condition. Therefore, it conclusive demonstrates that the stability of Cu\textsubscript{2}O/TNTs is good.
