1. General information

The electrodes were purchased from AIDAHENGSHENG, Tianjin. Potentiostats (ITECH IT6720) were purchased on JD.COM. The IKA ElectraSyn 2.0 was purchased from IKA China agent. Solvents were purchased from TONGGUANG CHEMICAL, Beijing or BEIJING CHEMICAL, in GR (or CCER). Purification of products was conducted by column chromatography on silica gel (200-300 mesh, for some cases 300-400 mesh were used, from Qingdao, China). NMR spectra were measured on a Bruker ARX400 (1H at 400 MHz, 13C at 101 MHz) magnetic resonance spectrometer. Chemical shifts (δ) are reported in ppm using tetramethylsilane as internal standard (s = singlet, d = doublet, t = triplet, q = quartet, dd = doublet of doublets, m = multiplet), and coupling constants (J) were reported in Hertz (Hz). GC-MS or FID data were measured using the Agilent Technologies 7890B GC and the Agilent Technologies 5977B MSD. The FID yields were all based on standard curves with 5 points and minimum 0.996 $R^2$ value (or 4 points and minimum 0.997 $R^2$ value). The CV experiments were performed using electrochemical analyzer CHI627E (manufactured by Shanghai Chenhua Apparatus Company). In situ EPR experiments were conducted using Bruker Elexsys E580 Spectrometer.

2.1 Preparation of diazonium salt (1a-1x)

The diazonium salts (1) were prepared according to literature procedure. Appropriate arylamine (S-1, 25 mmol) was dissolved in water (10 mL) and hydrofluoroboric acid (48% w/w in water, 10.5 mL, about 2.0 equiv). After the reaction mixture was cooled to 0 °C, sodium nitrile solution (1.73 g, 25 mmol in 6 mL water) was added dropwise. The reaction mixture was stirred at 0 °C for 40 min. The resulting precipitate was collected by filtration. The crude product was dissolved into acetone (about 20 mL, for some low solubility product, more acetone was used), and the solution was gently heated, and then diethyl ether was added until the recrystallized product precipitated completely. The diazonium salt 1 was collected by filtration, washed several times by cold diethyl ether and dried under vacuum.

3.2 Electrochemical Sandmeyer reaction of diazonium salts.

![Reaction Scheme]

In a 10 mL tube equipped with a stir bar, diazonium salt (1, 0.3 mmol), halogenation reagent and Bu$_4$NClO$_4$ (0.25 mmol, 85.5 mg) were dissolved in a mixed solvent of MeOH (2.5 mL) and DMF (0.5 mL), following with two Pt net electrodes were immerged. The reaction mixture was stirred at 20 °C, with constant current was continuous given for 3 h. The slightly modified conditions were given in each case.

Upon completion, for cases given the isolated yields, the reaction mixture was poured into diethyl ether (60 mL), washed with water two times (20 mL * 2). The combined water phase was extracted with diethyl ether for another time,
and the secondary organic phase was washed with water again. The combined organic phase was dried over Na$_2$SO$_4$, then the solvent was removed and the desired product was purified by column chromatography (silica gel).

For other cases, the salt in reaction mixture was removed by a small silica gel chromatography or extraction with diethyl ether and water. Then, internal standard substance was added (about 28 mg of n-decane for FID, or about 27 mg of 4-(Trifluoromethoxy)anisole for $^{19}$F NMR) and the yield was measured by GC-FID or $^{19}$F NMR directly.

The reaction mixture was stirred at room temperature for 3 h, with no current.
or 10 mA constant current was continuous given. After that, the reaction mixture was analyzed by GC-MS and the yield of 2a was measured by GC-FID.

4.4 Cyclic voltammetry (CV) experiments

In all cases, a mixture solvent of MeOH and DMF (5:1 v/v) contented Bu₄NCIO₄ (0.1 M) as electrolyte was used. The experiments used an L-shape glassy carbon electrode as the working electrode, a Pt wire as the counter electrode and a saturated calomel electrode (SCE) as the reference electrode. The electric potential was between +1.5 and -0.5 V vs SCE, with 0.01 V/s scan rate. For cases with a single reagent, the concentration was 5 mM (for 1a) or 10 mM (for NBS and TEMPO), while for cases with two reagents a tenfold concentration was required to increase the signal for their cooperative process.

5. EPR experiments and data

Bu$_4$NClO$_4$ (513 mg, 1.5 mmol) was dissolved in a mixed solvent of MeOH (12.5 mL) and DMF (2.5 mL). Two Teflon plugs were drilled 3 mm hole, Two Pt wires (0.2 mm diameter) were welded with general electric wires and passed through each plug.

For each case, PBN (21.3 mg, 0.12 mmol, 1.2 equiv), 1a (if necessary, 26.4 mg, 0.1 mmol, 1.0 equiv) and NBS (if necessary 35.6 mg, 0.2 mmol, 2.0 equiv) were dissolved in 1 mL of the prepared electrolyte solution. Then, the reaction mixture was added into a glass flat cell (0.3 mm thickness in the working area, with a liquid storage pot above, about 0.2 mL of solvent was required). The flat cell was closed using the plugs as mentioned above, meanwhile the Pt wires were stretched from each side as electrodes.

X-band cw-EPR spectra were measured on a Bruker Elexsys E580 spectrometer with a super-high-Q resonator at room temperature. In all cases, the Q values after sample loading were similar (1500 ± 300). The magnetic field scanning region was between 3420 and 3620 G and contained 1024 points. MW power was 9.464 mW and modulation amplitude was 1 G. A total of 300 spectra were acquired in a time course of ~ 100 min. In each case, the current was given in a constant voltage of 16 V since about 6 min after the experiment was began (in order to obtain a blank control at the beginning). The EPR spectra were simulated using the EasySpin-5.2.14 running in Matlab (R2017a).
