4. Conformational Analysis of Important Transition States

The presence of the dihexyl chains on the substrate gives way to numerous conformers. A detailed conformational search is thus undertaken to identify the most favorable geometry for both the C–H activation (**TS1**) and the reductive elimination (**TS2**) TSs. Here, certain key dihedral angles (Φ_1 , Φ_2 , Φ_3) as shown in Table S1 are changed and the corresponding TS geometries are re-optimized. The initial guess values of the dihedral angles are made in such a way that it belongs either to an *anti* (*a*) or a *gauche* (*g*) conformer along the hexyl chain. Thus, for a hexyl chain, three major combinations of the primary dihedral angles Φ_1 , Φ_2 , Φ_3 are considered. Within a primary dihedral, say Φ_1 , other combinations of *a* and *g* that differ in Φ_2 and/or Φ_3 values are likely. Further combinations of the *a* and *g* conformers are also possible. We have therefore considered *aaa*, *ggg*, *aga*, *agg*, *aag*, *gag*, *gaa* and *gga* conformers of both the hexyl chains of *N,N*-dihexyl substituent, to access the energetically most favorable geometries of

the transition states for C–H activation and reductive elimination leading to *meta*, *ortho* and *para* borylated products. Tables S1-S3 provide a compilation of the optimized dihedral angles and their corresponding energies.

Since *aaa* is found to be the most preferred conformer of the reductive elimination TS for the *meta* and *para* positions, we have considered the *aaa* conformer for *ortho* borylation as well.

6. Energetic Span Model

The energies of various stationary points are considered for the evaluation of the turnover frequency (TOF) of a catalytic cycle. The TOF in turn is determined by identifying the turnover determining intermediate (TDI) and turnover determining transition state (TDTS).¹ The energy span (δE) can then be calculated using the following equations:

$$\delta E = T_{\text{TDTS}} - I_{\text{TDI}} \quad (1), \text{ if the TDTS is after the TDI}$$

$$\delta E = T_{\text{TDTS}} - I_{\text{TDI}} + \Delta G_r \quad (2), \text{ if the TDTS is before the TDI}$$

where ΔG_r is the free energy of the reaction.

9. Distortion-Interaction/Activation-Strain (DI-AS) Analysis

The barrier height for an elementary step, calculated as the energy difference between the respective pre-reacting complex and the transition state is described in terms of the extent of distortion experienced by the reactants and the interaction between such distorted reacting partners (also referred to as fragments), both at the TS geometry. The destabilizing distortion energy $\Delta E_{\text{dis}}(\zeta)$ and the stabilizing interaction energy $\Delta E_{\text{int}}(\zeta)$ between the distorted fragments is equated to the activation energy as shown in equation (3). The DI-AS analysis includes calculation of the extent of distortion and interaction along the respective IRC trajectories.

$$\Delta E^\ddagger = \Delta E(\zeta^{\text{TS}}) = \Delta E_{\text{dis}}(\zeta) + \Delta E_{\text{int}}(\zeta) \quad (3)$$
