1. Experiment Section

1.1 Regents and equipment

All starting materials were purchased from Sigma-Aldrich and used without any purification. The composition and phase of the as-prepared products were acquired by the powder X-ray diffraction (XRD) pattern using a Bruker D8 diffractometer with CuKα radiation (λ=1.5418 Å) at room temperature. The morphology and crystal structure of as-prepared products were observed by scanning electron microscopy (Hitachi SU-8010 field emission SEM), and transmission electron microscopy (FEI Tecnai G20). All TEM samples were prepared by depositing a drop of diluted suspensions in ethanol on a carbon film coated copper grid. Thermogravimentric analysis (TGA) was carried on a TGA-Q500 thermoanalyzer with a heating rate of 10 °C/min under nitrogen atmosphere. The gas sorption isotherms were measured on an autosorp-IQ instrument from Quantachrome Instruments Corporation (Boynton Beach, Florida USA).

1.2 Synthesis of N-rich MOFs

In a typical synthesis,[1] a mixture of Co(OAc)₂·4H₂O (24.9 mg, 0.1 mmol), diimpym (21.8 mg, 0.1 mmol), and H₂npta (21.1 g, 0.1 mmol) were placed into a 25 mL Teflon reactor in the presence of 2 mL methanol-water (v:v = 1:1) and 50 μL 0.1 M NaOH, which was sealed and heated to 120 °C. The temperature was held for 3000 mins, and then the reactant mixture was cooled at a rate of 0.1 °C min⁻¹ to room temperature, forming prismatic black crystals of 1 (yield, 70%). IR (solid KBr pellet): ν = 3121 (w), 1626 (m), 1585 (s), 1533(m), 1484 (m), 1348 (m), 1330 (m), 1313 (m), 1274 (w), 1231 (m), 1142 (w), 1102 (w), 1063 (s), 992 (m), 939 (w), 917 (w), 860 (m), 786 (m), 728 (s), 646 (s), 614 (m), 543 (w), 518 (w), 486 (m) cm⁻¹. Elemental analysis calcd (%) for C₁₈H₁₁CoN₇O₆: C 45.02, H 2.31, N 20.42; found: C 45.12, H 2.51, N 19.91.

1.3 Synthesis of porous Co₃O₄/N-C

Co₃O₄/N-C composite was synthesized via calcination of the obtained N-rich MOF at 500 °C for 2 h in a N₂ condition with a slow heating rate of 0.5 °C·min⁻¹.[1] The resulting powder was black in color.

1.4 Synthesis of Nitrogen doped carbon honeycomb-like structure assembled by mesoporous nanosheets
NCH was synthesized by a one-step etching process by use HCl as the etchant. Typically, 10 mg as-prepared porous Co₃O₄/N-C was add to 8 mL H₂O and 2mL HCl mixed solution and, then transferred to 25 mL Teflon-lined autoclave and heated at 150 °C for 6 h. After the autoclave cooled to room temperature naturally, samples were collected by centrifugation, thoroughly washed with distilled water 5-6 times, and dried at 60°C. The method of directly etching N rich MOFs was similar as the obtained NCH. The difference was directly using N rich MOF as an etched substance.

1.5 Synthesis of Co₃O₄ by recovering etching solution (strategy 1)

The remaining liquid after etching was directly transferred to 25 mL teflon-lined autoclave in batches and heated at 200 °C for 10 h, then calcined the obtained products at 500 °C for 2 h.

1.6 Synthesis of N rich MOFs by recovering etching solution (strategy 2)

Taking 5 mL remaining liquid added in 5 mL methanol to form the mixture. 4,6-di(1H-imidazol-1-yl)pyrimidine (0.05 mmol), 5-nitroisophthalic acid (0.05 mmol) and 50 mL 0.1 M NaOH were added into above mixture. Then the mixture were placed into a 25 mL Teflon reactor and heated to 120 °C for 3000 mins. The products were collected as microcrystalline sample.

1.7 Electrochemical measurements.

The working electrode was fabricated through squeezing a mixture of binder (Polyacrylic acid, 50%), superconductive carbon black, and active materials, which the mixture weight ratio is 10: 20: 70. The mass loading of the active material is 0.8 mg/cm². Lithium was used as the reference and counter electrodes. 1 M LiPF₆ electrolyte dissolved in a mixture, which is composed with dimethyl carbonate (DMC), ethylene carbonate (EC) and ethyl methyl carbonate (EMC) (volume ratio of 1:1:1). The LAND-CT2001A instrument was used to measure the cycle life and electrochemical capacity of the working electrode by the galvanostatic method at the charge and discharge current density of 100 - 2000 mA·g⁻¹. The cut-off potential for charge/discharge was set at 0.01 and 3.0 V (vs. Li⁺/Li). All electrochemical measurements were performed at ambient temperature.

1.8 Theoretical calculated method.

The first-principles calculations were based on the Vienna ab initio simulation package (VASP). The projected augmented wave (PAW) method was used to describe the electron–ion
interactions.
