Fig. S4 (A) Variation of supercontraction ratio in three-step production procedure of graphene-coated spidroin fibres with wrinkles. (B) Visual comparison of natural spidroin fibres, supercontracted spidroin fibres and graphene-coated spidroin fibres with wrinkles.
Fig. S5 (A) SEM image of graphene-coated spidroin fibres with wrinkles but without supercontraction. (B) Elm bark.

Fig. S6 Electric evaluation of graphene-coated spidroin fibres with different wrinkle degrees. Wrinkle degree was controlled by $\varepsilon_{\text{contraction}} = \alpha$ value during the production procedure. (A) Current-voltage curves; (B) Calculated electric resistance; (C) Conductivity; (D) Calculation equations. ($R$: resistance; $L$: length of the fibre; $S$: cross section area of the fibre; $\rho$: electric resistivity; $\sigma$: electrical conductivity)
**Fig. S7** (A) Dependence of electric conductivity on strain and wrinkle degree for graphene-coated spidroin fibres. Wrinkle degree was controlled by $\varepsilon_{\text{contraction}}=a$ value during the production procedure. (B) Wrinkle variation during wet stretching and dry stretching processes.

**Fig. S8** (A) Dependence of relative resistance on strain. (B & C) Responsivity of electric current to force (B) and tensions (C). Electric modulus of rubber band (diameter ~2mm): $\sim$500 kPa.
Fig. S9 (A) Repaired response of tendril-like sensor with 10% strain. (B) Stability of tendril-like sensor under stretch-release cycle. Strain: 13%. (C) The current change curves of the last 10 cycles extracted from the red part in (B). (D) Rapid response of tendril-like sensor under 45° finger bending.

Sensing mechanism of the tendril-like sensor during stretching:

SEBS diameter, $2R=1.5$ mm; silk fiber diameter, $2r=0.095$ mm; initial length of SEBS rod, $H=10$ mm; maximum length of SEBS rod during sensing, $H'=11.37$ mm.

Here, the conductive silk fiber was wrapped on the SEBS rod turn-by-turn compactly, so the length of silk fiber in each turn could be calculated by:

$l = 2\pi R = 4.71$ mm

The number of turns, $N$, wrapped could be evaluated as:

$N = H/2r \approx 105$

Therefore, the length variation, $\Delta h$, of SEBS rod in each turn during sensing at the maximum
could be calculated as:

$$\Delta h = \frac{H - H'}{N} \approx 0.013 \text{ mm}$$

So, the length variation of conductive silk fiber, $l'$, in each turn could be calculated by unfolding the cylindrical surface in each turn:

$$\Delta h = 0.013 \text{ mm}$$

where angle $\alpha \approx 90^\circ$, and $l'$ could be calculated by:

$$l' = \sqrt{l^2 + \Delta h^2} = 4.710018 \text{ mm}$$

Therefore the length variation ratio of the whole conductive silk fiber could be calculated:

$$\frac{l' - l}{l} \times 100\% = 3.8 \times 10^{-4}\%$$

So the length variation ratio of the conductive silk fiber was very low, and the variation of ripples on the conductive silk fiber was also very very small. Based on the above analysis, most of the contribution to the resistance variation should be from fibre separation during stretching.
**Fig. S10** Variation of supercontraction ratio in three-step production procedure of graphene-coated spidroin fibres with overlapped cracks.

**Region I:** LBL GO coating & GO reducing
\[ \varepsilon_{\text{contraction}} = b \]

**Region II:** Stretching
\[ \varepsilon_{\text{contraction}} = 0 \]

**Region III:** Super-contraction
\[ \varepsilon_{\text{contraction}} = 45\% \]

**Fig. S11** (A) Electric conductivity of graphene-coated spidroin fibres with different degree of overlapped cracks. Overlapped cracks were controlled by \( \varepsilon_{\text{contraction}} = b \) value during the production procedure. (B) Schematic illustration of variation of overlapped cracks during stretching. \( R_g \) is inherent resistance of graphene sheath; \( R_O \) is resistance resulted by overlap. (C) Dependence of electric conductivity on strain under dry and wet conditions. Cracks were produced with \( \varepsilon_{\text{contraction}} = b \sim 20\% \).
**Fig. S12** (A) Responsivity of relative electric resistance of vibration sensor to ant motion. (B) Responsivity of relative electric resistance of vibration sensor to throat vibration during speaking different words. (C) Schematic illustration of variation of overlapped cracks during stretching and pressure.

**Fig. S13** FTIR spectra of GO and chemically reduced GO (rGO).
