Supporting Information

A difunctional metal organic framework with Lewis basic sites
demonstrating turn-off sensing of Cu$^{2+}$ and sensitization of Ln$^{3+}$

Materials and Instrumentation:
All chemicals were obtained commercially and used without additional purification. Single-crystal diffractometry was conducted on a Bruker Smart Apex CCD II area-detector diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. Elemental analyses (C, H, and N) were performed on a Perkin-Elmer 2400 CHN elemental analyzer and the metal contents were determined with a PLASMA-SPEC(I) ICP atomic emission spectrometer. IR spectra were recorded in the range 4000-400 cm⁻¹ on Mattson Alpha-Centauri spectrometer using KBr pellets. Thermal gravimetric (TG) analyses were performed on a Perkin-Elmer TGA7 instrument in flowing N₂ with a heating rate of 10 °C/min. Powder X-ray diffraction (XRD) measurements were performed on a Rigaku D/MAX-3 instrument with Cu Kα radiation in the angular range 2θ = 3°-50° at 293 K. Gas adsorption measurements were measured with Quantachrome Autosorb-iQ. The emission spectra were recorded using the F-4500 FL spectrophotometer.

Synthesis of [Zn(BPTC)₀.₈(Tz)]·DMF·CH₃OH (1):
A mixture of biphenyl-3,3',5,5'-tetracarboxylate (H₄BPTC, 17mg, 0.05 mmol), tetrazolate (Tz, 35mg, 0.5 mmol) and Zn(Ac)₂·2H₂O (30 mg, 0.15 mmol) were dissolved in 3 mL N,N-dimethylformamide (DMF) and 3 mL methanol(MeOH) and stirred for 10 minutes. Then the mixture was transferred into and sealed in a Teflon reactor (18 mL) and heated at 100 °C for 72 h. Colorless block crystals of the product were formed and collected by filtration and washed with DMF several times after the mixture was cooled to room temperature. Yield: 30 mg (~48.8% based on H₄BPTC). Elemental analysis for C₁₃H₁₅N₅O₆Zn (%): calcd. H: 3.75, C: 38.77, N: 17.39% found: H: 3.81, C: 38.69, N: 17.46%.

X-ray Crystallography:
Single-crystal diffractometry was conducted on a Bruker Smart Apex CCD II area-detector diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. The linear absorption coefficients, scattering factors for the atoms, and anomalous dispersion corrections were taken from the International Tables for X-Ray Crystallography. Empirical absorption corrections were applied. The structures were solved by using the direct method and refined through the full-matrix least-squares method on F2 using SHELXS-97. The total interstitial solvent molecule contents were determined by TGA.
Crystal data of 1: Monoclinic, Fw = 4128.19 g/mol, space group P2₁/c, Z = 4, a = 12.345 (5) Å, b = 9.502 (5) Å, c = 18.610 (5) Å, β= 99.448 (5) deg, V = 2153.4 (15) Å³, T = 293 (2) K, 11092 reflections measured, 3870 independent reflections (Rint = 0.0339). The final R1 values were 0.0806 (I> 2σ(I)). The final wR(F²) values were 0.2790 (I> 2σ(I)). The goodness of fit on F² was 1.098.

Gas adsorption experiment
The N₂ and CO₂ sorption measurements were performed on an automatic volumetric adsorption equipment (Quantachrome Autosorb-iQ). Before gas adsorption measurements, the synthesized sample was immersed in dichloromethane for 24 h,
and the extract was decanted. Fresh dichloromethane was subsequently added, and the crystals were allowed to stay for an additional 24 h to remove the dichloromethane solvates. After the removal of dichloromethane by decanting, the sample was activated by drying under a dynamic vacuum at 373 K overnight to obtain desolvated sample (donated as 1a). Before the measurement, 1a was dried again by using the ‘outgas’ function of the surface area analyzer for 12 h at 373 K.

**Experiment of sensing metal ions**

For the experiments of sensing metal ions, powder of 1a (3 mg) was immersed in methanol solutions containing $\text{MCl}_x$ ($10^{-1}$ M; $\text{M} = \text{K}^+, \text{NH}_4^+, \text{Cd}^{2+}, \text{Mn}^{2+}, \text{Ni}^{2+}, \text{Ba}^{2+}, \text{Co}^{2+}, \text{Cu}^{2+}$) as well as the same way used for the sensing in mixed metal ions (the concentration of $10^{-2}$ M for $\text{Cu}^{2+}$ ion and $10^{-1}$ M for other metal ions). Before photoluminescence measurements, the suspensions were oscillated for 30 min using ultrasonic waves to ensure uniform dispersion. For the titration experiments of $\text{Cu}^{2+}$ ion, 1a powder (3 mg) was immersed in methanol solutions contain other metal ions with the dropped addition of different concentrations of $\text{Cu}^{2+}$ in methanol.

**Encapsulation of lanthanide(III) ions in 1a:**

Desolvated compound 1 (50 mg) was soaked in the methanol solutions of the chloride salts of Eu$^{3+}$, Tb$^{3+}$, Sm$^{3+}$ and Dy$^{3+}$ (2 mL, 0.4 mmol). After soaking for 2 days, the crystals were washed with methanol several times to remove residual lanthanide(III) cations on the surface.
