Estimation of the enhancement factor

The SERS enhancement factor is determined as follows:

\[ EF = \frac{I_{\text{SERS}} \times N_{\text{SERS}}}{I_{\text{Bulk}} \times N_{\text{SERS}}} = \frac{I_{\text{SERS}}}{I_{\text{Bulk}}} \times \frac{S_{\text{laser}} \times h \times C \times N_A}{S_{\text{laser}} / S_{\text{MPY}}} \]

where \( I_{\text{SERS}} \) and \( I_{\text{Bulk}} \) represent the intensities of 4-MPY in the surface enhanced Raman spectra and Raman spectra respectively, and \( N_{\text{SERS}} \) and \( N_{\text{Bulk}} \) represent the corresponding number of molecules in the surface enhanced Raman spectra and Raman spectra, respectively. \( S_{\text{laser}} \) is laser spot size of 1 \( \mu \text{m} \). C is the corresponding concentration of 4-MPY used in the Raman spectra of 10.8 M (using the density 1.2 g/cm\(^3\) and molar mass 111.16 g/mol), h is the effective layer depth of 19 \( \mu \text{m} \). \( N_A \) is the Avogadro constant. \( S_{\text{MPY}} \) is the area of each 4-MPY molecule (\( \sim 7 \times 10^{-7} \mu \text{m}^2 \)). By dividing the laser surface area by the cross-sectional area per molecule. Thus, we can then obtain \( N_{\text{SERS}} \) is \( 9.70 \times 10^{10} \) and \( N_{\text{Bulk}} \) is \( 1.12 \times 10^6 \). The in-plane at 1576 cm\(^{-1}\) was chosen for calculation of the enhancement factor because it is intense in both spectra and is isolated from interference with nearby lines. From the observed spectra (text Figure. 5a) we obtain for the ratio of intensities \( I_{\text{SERS}} / I_{\text{Bulk}} = 30624/193 = 158.6 \). The resulting EF is estimated to be \( 1.36 \times 10^7 \).
