**General Methods**

All moisture sensitive reactions were performed under nitrogen with dried solvent using oven-dried glassware. Dry Toluene was distilled over Na with benzophenone and triethylamine was dried over 4 Å molecular sieves prior to use. All uncharacterised chemicals were obtained from commercial suppliers and used as received.

NMR spectra were collected at 298 K on a Bruker Avance III 400 (400 MHz for $^1$H, 101 MHz for $^{13}$C, 162 MHz for $^{31}$P, and 76 MHz for $^{77}$Se), Bruker Avance 600 (600 MHz for $^1$H, 151 MHz for $^{13}$C), and Bruker Ascend 700 (700 MHz for $^1$H, 176 MHz for $^{13}$C) spectrometers. Chemical shifts ($\delta$) are reported in ppm and coupling constants ($J$) are measured Hz. $^1$H and $^{13}$C{$^1$H} chemical shifts are reported relative to the relevant residual solvent, whereas $^{31}$P{$^1$H} and $^{77}$Se chemical shifts are reported relative to the external references ($\delta = 0.00$ ppm) H$_3$PO$_4$ and Me$_2$Se, respectively.

Diffusion NMR data was collected on a Bruker Avance 600 at 298 K fitted with a 5 mm CP TCI probe and z-gradient coil of $5.35 \times 10^{-4}$ T cm$^{-1}$ maximum field strength. The convection compensated pulse program, dstebpgp3s, was used to mitigate the low viscosity of $d_3$-acetonitrile. The gradient pulse length and diffusion time were determined individually for each sample by calibrating the parameters required for 95% signal attenuation at 95% gradient strength. All experiments were conducted by increasing the gradient strength from 2 - 90% in 16 equal steps. Diffusion data was processed by Dynamics Centre and the DOSYToolbox$^1$. Errors were estimated from the standard error of the regression model and compared with the diffusion coefficient range as indicated by the HR-DOSY plot. Hydrodynamic radii were calculated by the Stokes-Einstein equation using reported viscosity values for acetonitrile.$^2$

Small molecule HR-ESI MS was performed on a Waters LCT Premier OA-TOF mass spectrometer. Mass spectra for the assembled cages were acquired using a Thermo Orbitrap Elite fitted with a hybrid ion trap-orbitrap mass spectrometer under conditions adapted from Yang et al.$^3$ Samples were injected straight, without dilution, at approximately 0.7 mM, and into the ion source at a flow rate of 15 µL/min with a capillary temperature of 50°C. The ions were generated via ESI with a constant applied voltage of 5 kV in order to minimise fragmentation. Analyses including isotope matching and error estimation were performed using Thermo Xcalibur.

Small molecule single-crystal X-ray diffraction data was obtained using an Oxford Diffraction SuperNova diffractometer at 150 K. The data was collected and reduced with CrysAlisPro.$^4$
Diffraction data of the assembled cages was recorded on the MX-1 beamline at the Australian Synchrotron. The data was collected using BluIce\textsuperscript{5} and reduced with XDS\textsuperscript{6}. All structures were solved within Olex2\textsuperscript{7} by ShelXT\textsuperscript{8} with refinement by ShelXL\textsuperscript{9}. Additional graphics were generated using the program Mercury.

General Boc Deprotection Procedure:

The resulting residue was extracted into ethyl acetate (25 mL) and washed with saturated sodium bicarbonate solution (2 × 25 mL) and brine (25 mL). The organic phase was then dried over sodium sulfate before evaporating to dryness to obtain the freebase product.
