**Table S1** Enhancement factors (EFs) for some composite materials are reported in References

**References**

The details of Enhanced Factor Calculation are given as follows:

\[ EF = \left( \frac{I_{\text{SERS}}}{I_{\text{BULK}}} \right) \times \left( \frac{N_{\text{BULK}}}{N_{\text{SERS}}} \right) \]

where \( I_{\text{SERS}} \) and \( I_{\text{BULK}} \) are the integrated intensities of R6G molecules adsorbed on Ag/CdS NCs and \( 10^{-3} \) M of R6G bulk, respectively. \( N_{\text{SERS}} \) and \( N_{\text{BULK}} \) correspond to the number of R6G molecules adsorbed on the SERS substrate and in the bulk solution excited by the laser beam, respectively.

\( N_{\text{BULK}} \) is calculated by the following formula:

\[ N_{\text{BULK}} = \rho AhNa/M \]

where \( \rho \) correspond to the density of R6G molecules, \( A \) refer to the irradiation area under the laser beam (1 \( \mu \text{m} \) in diameter), \( h \) is the focal depth of the laser (9.9 \( \mu \text{m} \), \( h = (2\pi/633 \text{ nm})^2 (1 \mu \text{m})^2 \)). \( N_A \) is the Avogadro constant. \( M \) correspond to the molecule weight of R6G (479 g/mol)

\( N_{\text{BULK}} \) is calculated by the following formula:

\[ N_{\text{SERS}} = C_{\text{SERS}} V N_A A / \pi r^2 \]

where \( C_{\text{SERS}} \) correspond to the concentration of R6G molecules, \( V \) is the volume of one drop R6G molecules (20 \( \mu \text{L} \)), \( r \) is the diameter of the circle 20 \( \mu \text{L} \) R6G solution spread and completely dried (4 mm).
Details of LOD calculation are presented as follows:

A linear log plot of the corresponding Raman intensity at 1361 cm$^{-1}$ and R6G concentrations was established (see Fig.7c). The log-log plot of the Raman intensity $I_{1361}$ and R6G concentrations $C_{R6G}$ follows a linear relationship ($R^2 = 0.99$), log$_{10} (I) = -0.234 \log_{10}(C_{R6G}) + 4.759$. And the error bars in the picture are standard deviations of 3 different positions for each sample. It is obviously observed that the linear equations and correlation coefficients indicate that there are high correlations between Raman intensities and concentrations of R6G. The limits of detection is calculated to 10$^{-13}$ M by the formula,$^{1,2}$

$$\text{LOD} = \frac{3\sigma}{k}$$

Where $\sigma$ means the standard deviation of several times detection for pure SERS substrate, and $k$ represents the slope of the equation’s linear fitting.
