1 Method

1.1. Characterizations

X-ray diffraction analysis was performed on a DX-2600 X-ray diffractometer. The morphology and surface elements distribution of Pt/CdS/ZnO/CoO\textsubscript{x} graphene microtubule was observed by a scanning electron microscopy (SEM, JSM-7500F, Japan). Additionally, the Fourier transform infrared spectra were used to evaluate the surface functional groups of the samples (FTIR, Shimadzu-8400S, Japan) and the X-ray photoelectron spectroscopy (XPS, XSAM800, Britain) was applied to measure the
surface chemical composition, respectively. Raman spectra were acquired on a Raman system (Thermo Scientific, DXR Smart, USA). The UV-visible diffuse reflectance spectra (DRS, using BaSO₄ as the standard reference) were carried out on a Lambda75 UV-Vis spectrophotometer. Photoluminescence (PL) spectra were detected with FLS1000 Edinburgh Instrument. The electrochemical impedance spectroscopy (EIS) measurements were measured with an electrochemical workstation (CHI-660c, China).

2 Supplementary Results and Discussion

2.1 FTIR spectra and Roman spectra of samples

Fig. S1 (a) FTIR spectra of PCNZCo-GM and GO, (b) Roman spectra of PCNZCo-GM, PCNZCo-GM after reaction and GO, (c) SEM image of PCNZCo-GM after reaction

2.2 XPS analysis of samples

Fig. S2 (a) Full-scale XPS survey spectrum of PCNZCo-GM, (b, c) XPS spectra of C1s of GO and PCNZCo-GM and (d) XPS spectra of O1s of PCNZCo-GM.
2.3 Band-gap estimation

![Fig. S3 Plots of [F(R)hv]^2 vs. the energy of samples.]

As shown in Figure S4, the band gap energy of CdS and N-ZnO crystals were estimated to about 2.26 eV and 2.89 eV, respectively. Meanwhile, the band edge positions of conduction band (CB) and valence band (VB) of it can be calculated by the following Eqs. (2), (3):

\[
E_{CB} = X - E_C - 0.5E_g \quad (1)
\]

\[
E_{VB} = E_g + E_{CB} \quad (2)
\]

where, \(E_{CB}\) is the CB edge potential, \(E_{VB}\) is the VB edge potential, \(X\) is the electronegativity of the semiconductor, which is the electronegativity geometric mean of the constituent atoms (5.19 eV for CdS and 5.79 eV for ZnO), \(E_C\) is the energy of free electrons on the hydrogen scale (about 4.5 eV), and \(E_g\) is the band gap energy of the semiconductor. According to Eqs. (1) and (2), the CB and VB edge potentials of CdS are -0.44 eV and 1.82 eV, respectively, and N-ZnO are supposed to be -0.16 eV and 2.73 eV.
2.4 Photocatalytic ability of samples with different N-ZnO

![Graph showing degradation dynamics curves of PCNZCo-GM with different content of N-ZnO.

Fig. S4] The degradation dynamics curves of PCNZCo-GM with different content of N-ZnO. The respective amount of the N-ZnO precursors in the hybrid preparation is as follows: 0.6 mg/mL, 0.7 mg/mL, 0.8 mg/mL, and 0.9 mg/mL.

2.5 Total organic carbon (TOC) removal efficiency

![Graph showing total organic carbon (TOC) removal efficiency.

Fig. S5] Total organic carbon (TOC) removal efficiency during the photodegradation process.

2.6 Degradation dynamics curves and recycling tests of colorless BPA

![Graphs showing degradation dynamics and recycling tests of colorless BPA.

2.8 Photocatalytic performance comparisons of CdS or ZnO-based composites

Some researchers have reported the construction of CdS or ZnO-based heterojunctions, such as CF@ZnO/CdS, CdS/g-C₃N₄, RGO/ZnO, etc., which enhance the photocatalytic performance than single photocatalysts. Effective separation of charge and high cycle stability are key factors for photocatalysts application. In this paper, we prepared a spatially separated hollow Pt/CdS/ZnO/CoOₓ grapheme microtube (PCNZCo-GM) with a double cocatalysts by capillary and hydrothermal method for enhancing charge separation efficiency and photocatalytic oxidation ability. Our method has significant advantage compared with traditional methods because it enables easy inhalation of solution by capillary action and efficient separation of cocatalysts. In the spatial separation composite, Pt as electron collectors and CoOₓ as hole collectors were selectively decorated on the inner and outer surfaces of CdS/N-ZnO double-layered graphene microtubule (CNZ-GM), which prompts photogenerated electrons and holes near the surface to move in the opposite direction. The absorption range of ZnO can be significantly expanded by nitrogen doping and the charge separation can be effectively promoted by the
construction of Z-scheme heterojunction between CdS and N-ZnO. The hollow
graphene microtubule structure with an oxidation-reduction co-catalyst supported on
its inner and outer surfaces is conducive to simultaneous exposure of redox surface,
charge separation, reusability and mass transfer in photocatalytic process. Combining
other merits, such as excellent structural and functional characteristics of CdS and N-
ZnO, large surface area and surface reaction kinetics promoted by cocatalysts, the
PCNZCo-GM is an excellent photocatalyst of both photodegradation and disinfection.
Compared with other CdS or ZnO-based photocatalysts, the PCNZCo-GM exhibits a
more excellent photodegradation performance, rapider antibacterial performance and
higher recycling stability (Table S1). Consequently, the PCNZCo-GM shows a great
merit as a novel effective catalyst for water purification.
