2. Energetic span model

We have calculated the energy span using the energetic span model developed by Shaik and Kozuch which convey the turnover frequency (TOF) of a catalytic cycle using energetic of various stationary points. In the catalytic cycle, two states can be identified such as transition state and intermediate. The TOF of the catalytic cycle can be determined by these states. Therefore, the TOF of the catalytic cycle depends on the TOF-determining intermediate (TDI) and TOF-determining transition state (TDTS). The energy span δE can be calculated using the following equations:

$$\delta E = T_{TDTS} - I_{TDI} \quad (1), \text{ when the TDTS is after the TDI.}$$

3. Activation Strain Analysis

Following literature precedence, the activation barrier (ΔE^\ddagger) is splitting into (a) destabilizing distortion energy in the reactants (ΔE_d^\ddagger) and (b) stabilizing interaction energy between parallel distorted reactants (ΔE_i^\ddagger). The activation barrier can therefore be written as sum of the distortion and interaction energies, $\Delta E^\ddagger = \Delta E_d^\ddagger + \Delta E_i^\ddagger$. Distortion energy is calculated as the difference between the energies of the ground state geometries of undistorted reactants and the corresponding distorted structure in the transition state.

For this analysis, first we have access the reaction profile by performing the IRC calculations. After this single-point computations are done along the reaction coordinate. We have taken seven different points on the reaction coordinate to perform these calculations (**Figure S3**).

$$E_{\text{activation}} = E_{\text{distortion}} + E_{\text{interaction}}$$

$$E_{\text{distortion}} = [E_{f1(\text{TS})} + E_{f2(\text{TS})} + E_{f3(\text{TS})}] - [E_{f1} + E_{f2} + E_{f3}]$$

$$E_{\text{interaction}} = [E_{(\text{TS})} - E_{f1(\text{TS})} - E_{f2(\text{TS})} - E_{f3(\text{TS})}]$$

It is evident from the data given in Table S4 that the interaction energy is more stabilizing for the transition state [8a-9a][‡] as compared to that in [8-9][‡]. This can be mainly attributed to the larger number and more effective non-covalent interactions and hydrogen bonding present (O...H-C, C-H...π and N...H) in [8a-9a][‡] as shown in (AIM analysis).

For calculating the distortion energy, the overall system is divided into three fragments, f1, f2 and f3. In both the transition states f1 and f2 are same fragment, but f3 is different. In the transition state [8a-9a][‡] the one extra tosylamine molecule stabilized the transition state. Here we explain on the basis of strain model, out of three fragments which is more destabilized the distortion energy. It can be noted from Table S2 that there is not much difference in the distortion energy of fragment f1 and f2 for both the transition states. Therefore, it is the fragment f3 that is contributing appreciably to the destabilizing distortion energy. A closer look at the transition state structures reveals that the distortion originates mainly from the five membered nickelacycle (tosylamine molecule).
