**General**

All reagents and solvents were sourced from major commercial suppliers, and reactions were carried out in flame-dried glassware under an atmosphere of dry argon inside a glovebox or using Schlenk techniques.

Stock solutions (200 mL) were prepared using THF freshly distilled from potassium and 1,3,5-trimethoxybenzene (TMB, 3.36g, 20 mmol) dried in vacuo, and stored under argon for no longer than a week. Acetophenone was distilled, stored under argon and kept in the dark at room temperature.

Reagent grade triethylamine was dried over calcium hydride at 75 °C for 2 hours before being distilled at 105 °C under argon. Reagent grade formic acid was distilled under argon at 135 °C using a fractional distillation column, the first fraction of which was discarded.

Distilled formic acid (92.5 mL, 2.45 mol) was charged to a distillation apparatus with a dropping funnel attached. The formic acid was cooled to 0 °C and distilled triethylamine (136.5 mL, 0.98 mol) was charged to the dropping funnel and added to the formic acid dropwise over 1 hour. The mixture was then distilled at 145 °C and 5 mbar, and the ratio of components in the azeotropic distillate was confirmed by $^1$H NMR to be 5:2.

**Synthesis**

**Unsaturated complex 2**

Potassium tert-butoxide (2.2 mg, 0.020 mmol) was added to a solution of [(mesitylene)RuCl(R,R)-(TsDPEN)] in dry THF (1 mL of 2mM) to give a deep purple solution. The mixture was stirred for 5 minutes at room temperature. Passing through a 0.2 µm PTFE syringe filter yielded a 2 mM solution of 2 which was immediately analysed by UV-vis spectroscopy under argon to give a molar absorptivity of $\epsilon = 1380$ M$^{-1}$cm$^{-1}$ at $\lambda_{\text{max}} = 565$ nm.

![Figure S1: UV-vis absorption spectrum of unsaturated complex 2 at 2 mM in THF (0.5 cm optical path length).](image-url)
Hydride complex 4

Isopropanol (5 µL, 0.065 mmol) was added to a solution (1 mL of 16 mM) of complex 2 in d$_8$-THF yielding a yellow-brown solution leading to immediate formation of [(mesitylene)RuH($R,R$)-((TsDPEN)] (4) as confirmed by its characteristic $^1$H NMR resonances:

$^1$H NMR (500 MHz, 25°C, THF) δ = -5.59 (s, 1H, Ru-H), 2.03 (s, 3H, CH$_3$ in Ts), 2.22 (s, 9H, CH$_3$ in mesitylene), 4.03 (m, 1H, NHH), 4.37 (m, 1H, NHH), 4.83 (s, 3H, CH in mesitylene).

Figure S2: Partial $^1$H NMR spectrum for hydride complex 4 at 16 mM in THF (64 scans, 1.64 s acquisition time, 1 s delay time) with the characteristic Ru-H resonance highlighted in blue.
Formate complex 3

```
[(mesitylene)RuH(R,R)-(TsDPEN)] (4) in d₈-THF (1 mL of 16 mM) was charged to a pressure resistant NMR tube under argon and pressurised with 5 bar of CO₂. Upon mixing the yellow-brown solution turned bright yellow indicative of the formation of formate complex 3.¹

¹H NMR (500 MHz, 25°C, THF) δ = 2.21 (s, 3H, CH₃ in Ts), 2.28 (s, 9H, CH₃ in mesitylene), 5.25 (s, 3H, CH in mesitylene), 8.10 (s, 1H, OCHO), 9.06 (m, 1H, NH-H).
```

Analysis

FlowNMR Spectroscopy

Reactions were carried out in round-bottomed glass flasks with a magnetic stir bar under argon. A peristaltic pump (Vapourtec SF-10) was used to drive the reaction mixture around the flow path to a Bruker InsightMR flow tube inserted into a Bruker 500 MHz Avancell+ Ultrasield with a Prodigy BBO Cryoprobe. Polyetheretherketone (PEEK) tubing was used for the flow path (O.D. 1/16”, I.D. = 0.75 mm) and the flow tube (O.D. = 1/32”, I.D. = 0.125 mm). This tubing was connected to the reaction flask via a standard rubber seal with connections sealed using silicone grease. The system was heat regulated by two heat exchangers, one which connected to the flow path and the flow tube and a second which was connected to the reactor jacket (DrySyn Snowstorm ONE).

NMR spectra were acquired (number of scans: 8, acquisition time: 1.64 s, delay: 1 s, receiver gain: 4, lock: off) at 0 and 4 mL/min served to calculate integral correction factors accounting for flow effects using the following equations.

Equation 1: $I_{Corrected} = CF \times I$

Equation 2: $CF = I_{static}/I_{flow}$

Concentrations of species were then calculated by referencing peak integrals to the TMB internal standard.

Selectively excited $^1$H spectra were acquired at a much higher receiver gains than ordinary proton spectra (number of scans: 8, acquisition time: 2 s, delay: 1 s, receiver gain: 203, lock: off, constant 21: -6, constant 55: 3, O$_2$P: -5) and therefore require a correction factor to allow quantitative
comparison between peaks on the two different spectra. This was done by calculating a Reduced Integral Value (RIV) for the selectively excited hydride peak and then multiplying this by the concentration of the internal standard as per the following equations:\textsuperscript{2,4}

\[ RIV = \frac{I_{\text{hydride}} \times RG_{\text{normal}} \times RGCF}{RG_{\text{hydride}}} \]

Equation 3:

\[ [\text{Hydride}] = RIV \times \frac{[TMB]}{I_{\text{TMB}}/\text{Number of protons associated with TMB peak}} \]

Equation 4:

Where \( I_{\text{hydride}} \) = Integral of the hydride peak, \( RG_{\text{normal}} \) = receiver gain for selective excitation of internal standard, \( RG_{\text{hydride}} \) = receiver gain for selective excitation experiment of hydride, \( RGCF \) = Receiver gain correction factor calculated by plotting the integral of an internal standard of a range of receiver gains, \( I_{\text{TMB}} \) = integral of internal standard (TMB).

**Chiral HPLC**

Inserted into the flow path was a valve drive connected to the HPLC. The valve, sample loops and intermediate tubing between the flowpath and the HPLC was connected via HPLC standard stainless-steel tubing (I.D. 180 µm) and fittings. A 50 µL aliquot of reaction mixture was taken by the sample valve every 30 minutes. The sample was flowed to a secondary valve drive using an external pump (IPA at 0.25 mL/min). The secondary valve drive then resampled 5 µL of the original aliquot for analysis. This configuration was found to offer the highest quality chromatograms as a result of ‘refocussing’ the sample (eliminating peak tailing from back mixing), while also allowing for full customisability of solvent composition and sample dilution.

HPLC data was acquired using an Agilent 1260 Infinity II LC equipped with a Chiracell OD-H column (Daicell chiral, 250 mm length, 4.6 mm diameter, 5 µm particle size) which was preceded by a guard column (Chiracell OD-H 10 mm length, 4 mm diameter, 5 µm particle size) to prevent contamination. The eluent used was 9:1 hexane/IPA at 1 mL/min, and eluents were analysed using a UV detector at 254 nm.

Typical retention times (verified by injecting pure samples of each component) and peak separations were as shown in the example chromatogram below.
Enantiomeric excess was calculated using the following equation:

\[
\%ee = \frac{(R - S)}{(R + S)} \times 100
\]

**UV-Vis Spectroscopy**

UV-visible spectroscopic data was collected using an Ocean Optics fibre-optic setup consisting of a deuterium-halogen light source (DH-2000-BAL) connected to a 0.5 cm lensed PEEK SMA-Z flow cell and a QEPro spectrometer (10 µm slit) via SMA-terminated 400 µm solarisation-resistant light guides. OceanView 1.6.5 software was used for continuous spectral acquisition from 200 – 1000 nm resolution with an integration time of 10 ms and averaging 100 scans.

The light source was allowed to warm up for a minimum of 30 minutes prior to data acquisition. Modules within the OceanView software were used to acquire light and dark references and convert transmission to absorbance using the following equation:

\[
\text{Absorbance} = \log_{10} \left( \frac{\text{sample} - \text{dark reference}}{\text{light reference} - \text{dark reference}} \right)
\]

Equation 5

Once the references were taken data was set to save every minute and acquisition was started.
Headspace Mass Spectrometry

Headspace mass spectrometry data was collected using a Hiden HPR-20 R&D quadrupole mass spectrometer with a detection mass range of 1-300 amu coupled to QIC (Quartz Inert Capillary) fast sampling inlet. Relative sensitivities of H\textsubscript{2} and CO\textsubscript{2} in Ar were calibrated using a multiple calibration method in the Hiden quantitative gas analysis (QGA) software. The calibration mixtures used were 5% H\textsubscript{2}, 5% CO\textsubscript{2}, and 5% H\textsubscript{2} + 5% CO\textsubscript{2} in argon, respectively. The relative sensitivities of these gases were measured to be 2.27 (H\textsubscript{2}), 1.08 (CO\textsubscript{2}) and 1.00 (Ar). Gases present within the reaction mixture were identified by the scout spectra observed in S8 and S9 below.
Figure S8: Headspace mass spectrometry scout spectrum taken at t = 4 hrs during the asymmetric transfer hydrogenation of acetophenone (Mass range 0-50, 2 mM 1, 400 mM acetophenone, 1.05 mL formic acid/triethylamine 5:2 azeotrope, 3.71 mL 0.1 M TMB in THF at 40 ℃).

The QIC heating at 145°C and MS were allowed to stabilise for at least 30 minutes prior to acquisition. A blank test was carried out sampling air before switching to a method designed in the QGA software (Start range: 5, settle speed: normal, dwell speed: normal, electron energy: 70, emission current: 1). The PEEK sampler tubing was inserted through the rubber seal of the reaction flask, sealed with silicone grease and data acquisition was started. Argon was dosed to the reaction...
mixture at 30 L/hr and the QIC sampling inlet sampled at 16 cm³/min, data was acquired every 1.5 seconds for the masses of H₂ (2), CO₂ (44) and Ar (40).

Catalysis

General procedure for batch reactions
RuCl[(R,R)-TsDPEN(mesitylene)] (12.4 mg, 0.020 mmol) was charged to a Schlenk flask and dissolved in 7.43 mL of a stock solution of THF containing 1, 3, 5-trimethoxybenzene as an internal reference (0.1 M) and heated to 40 °C. Subsequently a 5:2 mixture of formic acid/triethylamine (2.10 mL) and acetophenone (0.467 mL, 4.0 mmol) were added to start the reaction. 0.3 mL of the reaction mixture were periodically withdrawn from the mixture to analyse reaction progress via ¹H NMR using the 1-phenylethanol CH quartet at 4.80 ppm and the acetophenone CH₃ singlet at 2.55 ppm versus the 6.08 ppm signal of the TMB standard (see Figure S10).

General procedure for flow runs
The flowtube and flowpath (outlined in black and red respectively in Figure S4) was purged with argon for a minimum of 30 minutes to ensure a dry and inert atmosphere. The systems heat control was turned on at this stage to allow for equilibration. The heat exchanger controlling the flow path and flow tube was set to 50 °C (to account for heat loss over the length of the system), the reaction vessel was heated to 40 °C and the NMR probe was set to 30 °C (improved shimming at this temperature).

The system was subsequently primed with a stock solution of THF containing 1,3,5-trimethoxybenzene as an internal reference (0.1 M) for 15 minutes at 4 mL/min. The PEEK tubing of the flowpath (in and out) was then pushed through the rubber seal of a Schlenk flask containing THF/TMB stock solution (5.43 mL) and 5:2 mixture of formic acid/triethylamine (2.10 mL). The solution was flowed through the apparatus for 10 minutes (4 mL/min) at 40 °C under an argon atmosphere to ensure homogeneity.

After inserting the flow tube into the spectrometer the flow was stopped. Frequency lock was disabled and automated shimming and tuning routines were applied. Flow was then resumed, and data acquisition (number of scans: 8, acquisition time: 1.64 s, delay: 1 s, receiver gain: 4, lock: off) started using and automated kinetic routine on InsightMR reaction monitoring software.

RuCl[(R,R)-TsDPEN(mesitylene)] 1 (12.4 mg, 0.020 mmol) dissolved in 2 mL of THF/TMB stock solution was added to the reaction vessel via syringe and the mixture was stirred for 15 minutes. At this point acetophenone (0.467 mL, 4.0 mmol) was added to start the reaction.
Additional Data
