Supporting Information

Fully Alternating Sustainable Polyesters from Epoxides and Cyclic Anhydrides: Economical and Metal-free Dual Catalysis

Experimental Procedures

Materials

All chemicals were used as received unless otherwise stated. Cyclohexane oxide (CHO), propene oxide (PO) and 1,8-diazabicyclo [5.4.0]undec-7-ene (DBU) were refluxed over CaH for 24 h and vacuum-distilled prior to use. Phthalic anhydride (J&K, 98%), maleic anhydride (TCI, >99%) and succinic anhydride (J&K, 99%) were purified by sublimation. Triclocarban (TCI, 98%), N,N'-diphenylurea (TCI,98%), N,N'-dicyclohexylurea (TCI, 98%), 1-cyclohexyl-3-phenyl-urea (Fuyuan Technology company, 98%), 1-cyclohexyl-3-phenyl-thiourea (J&K, 98%), bis(triphenylphosphine)iminium chloride([PPN]Cl) (Alfa, 97%), tetrabutylammonium bromide (NBu4Br) (Alfa, 98%) and 4-dimethylaminopyridine (DMAP) (Alfa, 99%) were used as received.

Measurements

$^1$H NMR and $^{13}$C NMR spectra were obtained on a Bruker DRX-500 MHz NMR spectrometer using CDCl$_3$ or DMSO-d$_6$ as solvent. Matrix-assisted laser desorption/ionization time-of-flight mass spectroscopy (MALDI-TOF MS) were recorded on Bruker ultrafleXtreme type. The polymer sample in THF (10 mg/mL), $trans$-2-[3-(4-tert-butylphenyl)-2-methyl-2-propenylidene]malononitrile (DCTB) in
THF as matrix (10 mg/mL) and sodium trifluoroacetate in methanol (1 mg/mL) were mixed in a 10:1:1 volume ratio, and then 1 μL of mixed solution was spotted onto the sample plate before being air-dried. Molecular weight determinations were carried out using a waters gel permeation chromatography (GPC) system with chloroform as eluent. The GPC system was calibrated by a series of polystyrene standards with polydispersity of 1.02. The glass-transition temperatures ($T_g$) were measured by a differential scanning calorimeter (DSC, Netzsch Model 204). The samples were firstly heated at a heating rate of 10 °C/min and then cooled at a cooling rate of 10 °C/ min by liquid nitrogen, followed by second heating.

**General Procedure of Polymerization**

Polymerizations were performed in a 25 mL vial using an external heating bath. The vial was charged with a predetermined amount of (thio)urea (0.05mmol, 1 equiv), organic base (0.05mmol, 1 equiv), epoxide (10mmol, 200 equiv) and anhydride (5mmol, 100 equiv), which were kept stirring for 5 min at room temperature in an N$_2$-filled glovebox. The vial was sealed, taken out of glovebox, and then immersed in the heating bath under the predetermined temperature. After equilibration at the desired polymerization temperature, the polymerization started. After a desired period of time, the vial was removed from heat block and a 0.2 mL of aliquot was taken from the reaction mixture and prepared for $^1$H NMR analysis. Then the mixture was dissolved in CHCl$_3$ and precipitated into 10-fold excess of methanol or hexane, filtered, washed with methanol or hexane to remove unreacted monomer, and dried in a vacuum oven at room temperature to a constant weight.

\(^a\) The copolymerizations were carried out at 110 °C in bulk, unless otherwise mentioned. \(^b\) PA conversion was determined by \(^1\)H NMR. \(^c\) Ester linkage was determined via \(^1\)H NMR by integrating ester and ether signals. \(^d\) \(M_n\) and PDI were determined by GPC. \(^e\) Performed in xylene, with a PA concentration of 5 mol/L. \(^f\) At 80 °C. \(^g\) Homopolymerization of CHO.
