Supporting information for “Active, Selective, and Stable Manganese Oxide Supported Atomic Pd Catalyst for Aerobic Oxidation of 5-Hydroxymethylfurfural”

1. Calculation of TOF values based on the interface of Pd/MnO$_2$

For the interface as active sites, the TOF values can be calculated according to the reference [1] by the specific rate in terms of the length of the perimeter of Pd/MnO$_2$ by assuming half sphere of Pd nanoparticles. For atomic Pd catalyst, the number of Pd atoms at the perimeter can be obtained from the loading amount.

The TOF based on the interface length between Pd and MnO$_2$ can be calculated according to the equation (1).

$$\text{TOF} = r_{\text{FDCA}} \times n_{\text{Pd}} \times N_A / N_{\text{Pd}}$$

(1)

$n_{\text{Pd}}$ was the weight percentage of Pd in the catalyst. $N_A$ is Avogadro constant.

The number of Pd atoms at the perimeter ($N_{\text{Pd}}$) can be calculated according to the equation (2).

$$N_{\text{Pd}} = L / d$$

(2)

$L$ can be calculated according to the equation (3).

$$L = 2\pi R \times N$$

(3)

The number of Pd particle at the interface ($N$) can be calculated according to the equation (4).

$$N = 1.32 \times 10^{19} \times (4/3\pi R^3/A) / (1/2 \times 4/3\pi r^3)$$

(4)

$R$ and $r$ represent the radius of Pd particle (~1.00 nm) and Pd atom (0.179 nm), respectively. $A$ is the volume correction factor of 0.74 (space utilization of the closed-pack atoms in metal nanoparticles).
2. Reaction kinetic model for Pd-species-dependent HMF oxidation

By following the evolution of the reaction with time, different products were detected in Figure 4 (a and b) of the text. The catalytic oxidation of HMF can expressed from the proposed mechanistic model (Scheme 1) with the assumption that the first oxidation of HMF gives both DFF and HMFCA.

Scheme 1. Reaction pathway for HMF oxidation to FDCA.

Equations (1)–(5) give the rate equations for each species consumed and produced, where $C_{\text{HMF}}, C_{\text{HMFCA}}, C_{\text{FFCA}},$ and $C_{\text{FDCA}}$ are the concentrations of each compound, and $k_1$–$k_5$ are the rate constants of each reaction step $^{[2, 3]}$.

\[
\frac{dC_{\text{HMF}}}{dt} = -(k_1+k_2)C_{\text{HMF}} \quad (1)
\]
\[
\frac{dC_{\text{HMFCA}}}{dt} = k_1C_{\text{HMF}} - k_3C_{\text{HMFCA}} \quad (2)
\]
\[
\frac{dC_{\text{FFCA}}}{dt} = k_2C_{\text{HMF}} - k_4C_{\text{DFF}} \quad (3)
\]
\[
\frac{dC_{\text{FDCA}}}{dt} = k_5C_{\text{HMFCA}} + k_4C_{\text{DFF}} - k_5C_{\text{FFCA}} \quad (4)
\]
\[
\frac{dC_{\text{FDCA}}}{dt} = k_5C_{\text{FDCA}} \quad (5)
\]

The least squares fitting algorithm of MATLAB lsqcurvefit was used to estimate the kinetic parameters, with the assumptions that:
1) the reaction temperature is regulated and assumed to be stable throughout the experiment at 100 °C;
2) the properties and the amount of the active species of the catalyst remain constant during the catalytic reaction the amount of the active species of the catalyst is constant;
3) the gem-diol form of the aldehyde group is unstable, and the equilibrium is shifted to carbonyl form;
4) all dehydrogenation reactions are irreversible;
5) the oxygen concentration is constant in the liquid phase and oxygen is sufficiently available.
