1. Preparation of screening compounds

1.1. General experimental

Commercially available starting materials were obtained from Sigma–Aldrich, Acros, Fluorochem and Alfa Aesar. Scaffolds 6b–i (Figure 1) were synthesised according to literature procedures.¹ All non-aqueous reactions were performed under nitrogen atmosphere unless otherwise stated. Water-sensitive reactions were performed in anhydrous solvents in oven-dried glassware cooled under nitrogen before use. Anhydrous dichloromethane (DCM), anhydrous tetrahydrofuran (THF), anhydrous toluene, anhydrous ethanol, anhydrous methanol and anhydrous acetonitrile were obtained from a PureSolv MD5 Purification System. All other solvents used were of chromatography or analytical grade. Petrol, TBD, DBU, TFA and NBS refers to petroleum spirit (b.p. 40–60 °C), triazabicyclodecene, 1,8-diazabicyclo[5.4.0]undec-7-ene, trifluoroacetic acid and N-bromosuccinimide respectively. An IKA RV 10 rotary evaporator was used to remove the solvents under reduced pressure.

Thin layer chromatography was performed using aluminium backed silica (Merck silica gel 60 F254) plates obtained from Merck. Ultraviolet lamp ($\lambda_{\text{max}} = 254$ nm) and KMnO₄ were used for visualization. Flash column chromatography was performed using silica gel 60 (35–70 μm particles) supplied by Merck. Strong cation exchange solid phase extraction (SCX-SPE) was performed using pre-packed Discovery DSC-SCX cartridges supplied by Supleco. Perkin-Elmer One FT-IR spectrometer was used to analyse the infrared spectra. Absorptions are reported in wavenumbers (cm⁻¹). Melting points (m.p.) were determined using Stuart melting point apparatus SMP3. A Bruker Daltonics microOTOF spectrometer with electrospray (ES) ionisation source was used for high-resolution mass spectrometry (HRMS).

Proton (¹H) and carbon (¹³C) NMR data was collected on Bruker 300, 400 or 600 MHz spectrometers. Data was collected at 300 K unless otherwise stated. Chemical shifts (δ) are given in parts per million (ppm) and they are referenced to the residual solvent peak. Coupling constants (J) are reported in
Hertz (Hz) and splitting patterns are reported in an abbreviated manner: app. (apparent), s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad). Assignments were made using COSY, DEPT, HMQC and NOESY experiments.

**General Procedure A**

By modification of an existing procedure, LiCl (2.15 eq) was added to acetonitrile (0.23 M) and the resulting suspension was stirred overnight at rt. Subsequently, the aldehyde derivative \( S1 \) (1.00 eq), the phosphonate derivative (1.32 eq) and DBU (1.10 eq) were added. After stirring the reaction mixture for 4 h at rt, a saturated aqueous solution of NaHCO\(_3\) (9 mL per 1.00 mmol of the aldehyde derivative) and EtOAc (5 mL per 1.00 mmol of the aldehyde derivative) were added. The phases were separated and the aqueous phase was extracted with EtOAc (3 \( \times \) 2 mL per 1.00 mmol of the aldehyde derivative)). The organic phases were combined, dried (MgSO\(_4\)), filtered and concentrated under reduced pressure to give a crude material.

1.3. Preparation of the nine optimised screening compounds

1.3.1. Experimental for the preparation of the aminoquinoline esters

General Procedure H

NBS (1.00 eq) was added to a solution of the respective ester derivative (1.00 eq) in THF (0.33 M) and the reaction mixture was stirred for the specified time at rt. The solution was concentrated under reduced pressure to give a crude material.

General Procedure I

According to a modified procedure, 6 2-methylbenzeneboronic acid (1.10 eq) and Na₂CO₃ (2.00 eq from a 1.00 M aqueous solution) were added to a solution of the respective brominated derivative (1.00 eq) in 1:2 ethanol:toluene (0.31 M). Subsequently, Pd(PPh₃)₄ (0.05 eq) was added and the reaction mixture was stirred at 80 °C. After 1.5 h, the mixture was allowed to cool to room temperature and water (2 mL per 1.00 mmol of the brominated derivative) and EtOAc (2 mL per 1.00 mmol of the brominated derivative) were added. The phases were separated and the aqueous phase was extracted with EtOAc (3 × (2 mL per 1.00 mmol of the brominated derivative)). The organic phases were combined, dried (MgSO₄), filtered and concentrated under reduced pressure to give a crude material.

1.3.2. Experimental for the decoration of the scaffolds

General Procedure J (Method D followed by A and B in main text)

By modification of an existing procedure,3 TFA (17.0 eq) was added to a solution of the carbamate derivative 6e (1.00 eq) in DCM (9.00 mL for each 1.00 mmol of the carbamate derivative 6e). The mixture was stirred at rt for 1 h and it was concentrated under reduced pressure. Afterwards, toluene (8.00 mL for each 1.00 mmol of the carbamate derivative 6e), Et\textsubscript{3}N (18.0 eq), TBD (0.50 eq) and the specified ester derivative (1.05 eq) were added and the reaction mixture was stirred for 18 h at 75 °C. Finally, the solvent was removed under reduced pressure to yield an intermediate crude material,
which was loaded into a silica pad, eluted with the specified eluent and concentrated under reduced pressure. The resulting product was treated with TFA (0.50 mL) and stirred at 75 °C for 3 h under air atmosphere. Subsequently, the mixture was concentrated under reduced pressure and it was loaded into a SCX pad, which was eluted with MeOH and with a solution of saturated NH₃ in MeOH. The fraction containing the saturated solution of NH₃ in MeOH was collected and concentrated under reduced pressure to yield a final crude material.

**General Procedure K (Method C followed by D, A and B in main text)**

By modification of existing procedures,³ NaOMe (0.10 eq of a 0.5 M solution in MeOH) was added to a solution of the acetate derivative 6d (1.00 eq) in MeOH (10.0 mL for each 1.00 mmol of the acetate derivative 6d). After stirring for 45 min at rt, the solvent was removed under reduced pressure. Subsequently, DCM (10.0 mL for each 1.00 mmol of the acetate derivative 6d) and TFA (24.0 eq) were added, the mixture was stirred at rt for 1 h and it was concentrated under reduced pressure. Afterwards, toluene (9.00 mL for each 1.00 mmol of the acetate derivative 6d) and the specified ester derivative (1.05 eq) were added. Subsequently, Et₃N (26.0 eq) and TBD (0.50 eq) were added and the reaction mixture was stirred for 18 h at 75 °C. The solvent was removed under reduced pressure to yield an intermediate crude material, which was loaded into a silica pad, eluted with the specified eluent and concentrated under reduced pressure. The resulting product was treated with TFA (0.50 mL) and stirred at 75 °C for 3 h under air atmosphere. Subsequently, the mixture was concentrated under reduced pressure and it was loaded into a SCX pad, which was eluted with MeOH and with a solution of saturated NH₃ in MeOH. The fraction containing the saturated solution of NH₃ in MeOH was collected and concentrated under reduced pressure to yield a final crude material.

**General Procedure L (Method E followed by A and B in main text)**

By modification of an existing procedure,³ hydrogen gas was passed through a mixture of the carbamate derivative 6i (1.00 eq) and Pd (0.03 eq of a 10% Pd/C) in MeOH (9.00 mL for each 1.00 mmol of the carbamate derivative 6i)
for 1 h at rt. Subsequently, the suspension was filtered through a pad of celite and the solvent was removed under reduced pressure. Toluene (9.00 mL for each 1.00 mmol of the carbamate derivative 6i), the specified ester derivative (1.05 eq) and TBD (0.50 eq) were added and the reaction mixture was stirred for 18 h at 75 °C. Finally, the solvent was removed under reduced pressure to yield an intermediate crude material, which was loaded into a silica pad, eluted with the specified eluent and concentrated under reduced pressure. The resulting product was treated with TFA (0.50 mL) and stirred at 75 °C for 3 h under air atmosphere. Subsequently, the mixture was concentrated under reduced pressure and it was loaded into a SCX pad, which was eluted with MeOH and with a solution of saturated NH₃ in MeOH. The fraction containing the saturated solution of NH₃ in MeOH was collected and concentrated under reduced pressure to yield a final crude material.

2. Determination of biological activity

2.1. Experimental for the determination of the biological activity

The derived compounds were assessed using a BACE1 red-shifted fluorescence-quenching assay kit supplied from ThermoFisher Scientific (PanVera®, Part Number P2985). The kit was composed of a “Swedish” mutant APP peptide tagged with a rhodamine derivative (fluorescence donor) and a proprietary quencher (rhodamine-EVNLAEFK-quencher) in a 75 μM aqueous solution of 50 mM ammonium bicarbonate (PanVera®, Part Number P2986); purified baculovirus-expressed BACE1 in a 50 mM aqueous solution of tris(hydroxymethyl) aminomethane (pH 7.5) with 10% glycerol (PanVera®, Part Number P2947); and an assay buffer of 50 mM aqueous solution of sodium acetate (pH 4.5) (PanVera®, Part Number P2948). The assay was performed using black 384 round-bottom well plates (Corning®, Part number 4514).

The assay procedure was adapted from an existing protocol. The BACE1 solution and the substrate solution provided were diluted in assay buffer to obtain 1 protein unit/mL and a 750 nM solution, respectively, as working solutions. The corresponding derived molecules were dissolved in DMSO (supplied by Sigma–Aldrich) to obtain a 200 mM or 100 mM solution. Lower concentrations of the derived compounds were achieved by serial dilution in DMSO in 10–12 steps to obtain different concentrations until 0.30 mM. Finally, each concentration in DMSO was diluted 100-fold with assay buffer to obtain the working solutions. For determination of inhibition activity, 5 μL of each of the working solutions (compound, BACE1 and substrate) was added to each well to obtain a total volume of 15 μL/well. For the positive control, a 1% DMSO solution in assay buffer was used instead of the working solution of the compounds. For the negative control, 1% DMSO solution in assay buffer and assay buffer were used instead of the working solutions of the compounds and BACE1. The compounds were added to the wells first, followed by the protein and 20 min later by the substrate. Each well was repeated in triplicate (Figure 2). The enzyme inhibition was measured at 25 °C by quantifying the fluorescence released using an Envision™ 2013 multilabel plate reader.
(PerkinElmer), with BODIPY TMR mirror, $\lambda_{\text{excitation}} = 531$ nm and $\lambda_{\text{emission}} = 595$ nm. The measurements were taken every minute over 2 h.

**Figure 2:** Well plate layout to assess BACE1 inhibition. The + and – means positive and negative control, respectively. Positive control does not contain compounds and negative control does not contain protein nor compounds. **Panel A:** First fluorescence-quenching assay to identify if the derived compounds 2 and 7–18 were inhibitors at 100 μM. **Panel B:** Successive fluorescence-quenching assays to determine the IC$_{50}$ of the inhibitors 9, 10 and 14 identified in the previous assay in panel A, the reference inhibitor 2 and the successive optimised inhibitors 22–30.

All the data was processed using Graphpad Prism V.6 (Graphpad Software Inc. CA). To process the data the average value of fluorescence unit for each compound at the specific concentration, for the negative control and for the positive control was plotted against the time. A linear fit was applied, the slopes were obtained and the % of inhibition was determined (Equation 1).
Equation 1: Calculation of the % of inhibition from the slopes.

The % of inhibition was reported as mean of the triplicate ± SEM (standard error of the mean). The dose-response data, expressed as % of inhibition vs log[compound] was represented with a sigmoidal dose-response model. This sigmoidal dose-response model allowed the determination of the IC\textsubscript{50} (Table 1). The values were calculated from three independent experiments.

4. Docking studies

4.1. Molecular docking studies

Protein preparation and molecular docking were carried out using GoldSuite (‘Genetic Optimisation for Ligand Docking’; The Cambridge Crystallographic Data Centre, United Kingdom). Protein structures were extracted from RCSB Protein Data Bank (RCSB.org) and subsequently prepared for docking using Hermes 1.9.3. Hydrogen atoms were first added to the protein structure, followed by removal of water molecules and ligand(s). Molecular docking was performed using Gold 5.6.3. The binding site was defined based on the conserved catalytic residues (Asp32 and Asp228) with a defined radius of 12 Å. Due to reported high mobility of Tyr71, side chain flexibility was introduced and four possible side chain rotamers (Table 2) were generated prior to docking. Two additional docking constraints based on previous protein co-crystal structures were introduced: (1) Asp32 and Asp228 were required to form H-bond(s), and (2) 2-aminooquinoline (PDB: 2OHL) was used as substructure template. The model was examined using PyMOL (version 2.0 Schrödinger, LLC) through visual inspection.
