Biological assay protocols and data

Biofilm inhibition assay. *M. smegmatis* was grown in 7H9 (ADC, 0.5% Tween 80) for 48 h and this culture was used to inoculate Difco M9 minimal salts media (OD600=0.01) supplemented with glucose (20% Sigma-Aldrich, 2 mL per 100 mL), MgSO₄ (1 M, 200 µL per 100 mL), and CaCl₂ (1 M, 10 µL per 100 mL). 100 µL per well of the subculture was aliquoted into the center two columns of a 96-well PVC microtiter plate. Columns 1 and 12 served as negative control wells. Then compound from DMSO stock solutions was added to aliquots of the subculture to give the desired concentration to be tested and aliquoted (100 µL per well) into the remaining wells of the 96-well PVC microtiter plate. Sample plates were then wrapped in GLAD Press n'Seal and were incubated under stationary conditions for 48 h at 37 °C. After incubation, the media was discarded, and the plates were washed thoroughly with water. The wells were stained with 110 µL of a 0.1% solution of crystal violet and then left at ambient temperature for 30 min. Crystal violet solution was discarded and plates washed thoroughly with water. 200 µL of 95% ethanol was added to each well, and the plates left covered at ambient temperature for 10 min. 125 µL of the ethanol solution was transferred to a polystyrene microtiter plate. Biofilm inhibition was quantified by measuring the OD₅₄₀ of each well. The values obtained from the two negative control lanes were subtracted from the OD₅₄₀ of the other columns.

Hemolysis Assay. Was performed on mechanically difibrinated sheep blood (Hemostat Laboratories: DSB100). Difibrinated blood (1.5 mL) was placed into an Eppendorf tube and centrifuged for 10 min at 10,000 rpm. The supernatant was removed and then the cells were resuspended in 1 mL of phosphate-buffered saline (PBS). The suspension was centrifuged as before, the supernatant removed, and the cells were resuspended two more times. The final cell suspension was diluted 10-fold. Compound was added from a DMSO stock solution to aliquots of the 10-fold suspension dilution of blood to give the desired concentrations to be tested. Triton X (1%) was used as a positive control (100% lysis). PBS was used as a negative control (zero hemolysis). Samples were placed in an incubator at 37 °C with shaking at 200 rpm for 1 h. After 1 h, the samples were centrifuged for 10 min at 10,000 rpm. The resulting supernatant was diluted by a factor of 40 in distilled water. The absorbance of the supernatant was then measured with a UV spectrometer at 540 nm.

**Time kill curves.** *M. smegmatis* was grown in 7H9 (ADC, 0.5% Tween80) for 48 h, and this culture was used to inoculate Difco M9 minimal salts media (OD600=0.01). Aliquots (3mL) were placed in culture tubes and dosed with compound from stock solutions in DMSO. Untreated inoculated media served as the control. Tubes were incubated at 37 °C with shaking. Samples were taken at 4, 8, 24, and 48 h time points, serially diluted in fresh M9, and plated on 7H10 plates. Plates were incubated at 37 °C for 48 h, and the number of colonies were counted.

**Bacterial strains.** The *Mycobacterium smegmatis* strain (ATCC 700084, mc₂155) was obtained from ATCC (Manassas, VA). Stock cultures were stored in glycerol stock media (25% v/v glycerol and 7H9, ADC, Tween 80) and maintained at -80 °C. The strain was maintained and cultured in
7H9 or on 7H10 agar (OADC, glycerol) until utilized in the assays outlined above. All assays were run in duplicate and repeated at least two separate times. All compounds were dissolved as their HCl salts in molecular biology grade DMSO as 10 or 100 mM stock solutions and stored at -20 °C.

**Figure S1.** Time kill curve for compounds 4l and 4q against *M. smegmatis*. Both compounds were tested at 60 μM.
Chemistry experimental and characterization

General remarks. All reagents used for chemical synthesis were purchased from commercially available sources without further purification. Flash chromatography was performed using 60 Å mesh standard grade silica gel from Sorbetch. NMR solvents were obtained from Cambridge Isotope Labs and used as is. All 1H NMR (300 or 500 MHz) were recorded at 25°C on Varian Mercury spectrometers or a (700 MHz) Bruker Avance spectrometer. All 13C NMR (101, 126, or 151 MHz) spectra were recorded at 25°C on Varian Mercury spectrometers or a (175 MHz) Bruker Avance spectrometer. Chemical shifts (δ) are given in parts per million (ppm) relative to the respective NMR solvent; coupling constants (J) are in hertz (Hz). Abbreviations used are s, singlet; d, doublet; dd, doublet of doublets; t, triplet; q, quartet; p, pentet; h, hextet; m, multiplet. All high-resolution mass spectrometry measurements were made in the Molecular Education, Technology, and Research Innovation Center (METRIC) at NC State University. Infrared spectra were obtained on a FT/IR-4100 spectrophotometer (vmax in cm⁻¹). UV absorbance was recorded on a Genesys 10 scanning UV/visible spectrophotometer (λmax in nm).

Procedure for 2-amino-6-nitroquinazoline formation (2). Commercially available guanidine carbonate (1g, 8.28 mmol, 1.4 eq) and 2-fluoro-5-nitrobenzaldehyde (1 g, 5.91 mmol, 1 eq) were dissolved in acetonitrile (100 mL) over molecular sieves. K2CO3 (1.14 g, 8.28 mmol, 1.4 eq) was added and the reaction was heated to 72 °C for 16 h. The molecular sieves were removed, and the reaction mixture was concentrated and then dissolved in ethyl acetate. The mixture was filtered, then the filtrate was washed with sat. NaHCO3 then the filtrate was washed with sat. NaHCO3 and then dissolved in ethyl acetate. The mixture was filtered, and the reaction was heated to stir at room temperature for 8 h. The reaction was filtered over celite and washed with ethyl acetate (20 mL x 2). The orange solid was isolated without further purification to yield, 2,6-diaminoquinazoline (3).
