Supplementary Discussions

Optimization of the BC nanofibres dispersion

The condition of fiber dispersion is one of the vital factors on the structure construction of Voronoi-like nanonets. To ensure the uniformity of nanonets, BC nanofibers dispersion must stable. Fig. S2 shows the effect of dispersed methods on the stability of BC nanofibers dispersion. It can be seen that, BC nanofibers dispersion obtained by high-speed homogenization became nonuniform after setting 3 h. Whereas, BC nanofibers dispersion obtained via high-pressure homogenization was still uniform and stable even after 8 h. Meanwhile, compared with BC nanofibers obtained by high-speed homogenization, which showed more entanglement, BC nanofibers obtained by high-pressure homogenization were demonstrated more homogeneous, resulting in the corresponding BC membrane with uniform Voronoi-like nanonets (Fig. S3).
