1. Experimental Section

Synthesis of cobalt boride (CoB) and iron boride (FeB)

All chemicals were used as received. The CoB and FeB were synthesized by a Sn/SnCl₂ redox assisted solid-state method. For the synthesis of CoB, 1 mmol anhydrous CoCl₂, 2 mmol B, and 1 mmol Sn powder were mixed together in the glove box and then pressed into pellet. While 1 mmol FeCl₃, 2.5 mmol B and 1.5 mmol Sn were used to prepare the pellet for FeB. Each pellet was then sealed in a quartz ampoule, and heated at 800 °C for 8 h with the ramping rate of 2 °C/min. After reaction, dark products were dispersed into ~10% con. HCl, after which the products were washed with deionized water and ethanol in succession for several times. The final CoB and FeB powders were obtained after drying them at 120 °C for 12 h.

Synthesis of Tungsten trioxide (WO₃) photoanodes

The bare WO₃ thin films were hydrothermally grown on fluorine doped tin oxide (FTO) coated glasses (2.2 mm thick, Sigma-Aldrich) by a modified route. Prior to the synthesis, FTO substrates were ultrasonically cleaned in acetone, ethanol, deionized water for 10 min each, and then dried at room temperature. For the synthesis of WO₃ thin films, 5 mL of 0.1 M Na₂WO₄·2H₂O solution and 10 mL of 0.1 M H₂C₂O₄·2H₂O solution were mixed under vigorous stirring. After stirring for extra 5 min, 10 mL of 1 M HCl was added into the above mixture and kept stirring for 10 min. 6 mL of the mixed solution was transferred to a 20 mL Teflon-lined stainless steel autoclave, where a FTO substrate (3 cm × 1.5 cm) was placed at an angel against the wall with the conducting side facing down. The autoclave was tightly sealed and heated at 180 °C for 2 h, then the FTO glass was cautiously washed and dried. The monoclinic WO₃ thin film grown on FTO substrate could be obtained after annealing the substrate at 550 °C for 1 h.

Loading of CoB or FeB on WO₃ photoanodes

The WO₃/CoB and WO₃/FeB photoanodes were fabricated by drop-casting. 2 mg metal boride powder was ultrasonically dispersed in 10 mL absolute ethanol for 15 min to form a suspension. Then 10 μL of the suspension was drop-casted on the surface of the WO₃ photoanode. By repeating the drop-casting process, the desired amount of the metal boride catalysts could be loaded on the electrodes. The as-prepared electrodes were finally dried in vacuum and then kept in the dark. For comparison, CoB and FeB powders were also drop-casted identically on the bare FTO substrates.

Loading of cobalt borate (Co-B₃) on WO₃ photoanodes

The Co-B₃ nanosheet was synthesized by the method reported previously. Typically, 5 mL of 0.5 M NaBH₄ solution was added into 100 mL of 0.1 mM Co(NO₃)₂·6H₂O solution and maintained at room-temperature for 40 min under vigorous stirring. After reaction, the dark product was collected by centrifuging, washing and drying overnight. For the fabrication of WO₃/Co-B₃ photoanodes, Co-B₃ powder was ultrasonically dispersed in absolute ethanol (200 μg/mL) and 10 μL of the suspension was drop-casted on the surface of the WO₃ photoanode. The desired amount of Co-B₃ catalysts could be loaded on the electrodes by repeating the drop-casting process. After drying in vacuum, the electrodes were kept in dark for further characterization.

Loading of cobalt hydroxide (Co(OH)₃) on WO₃ photoanodes

The WO₃/Co(OH)₃ photoanodes were obtained by a successive ionic layer adsorption and reaction method. The WO₃ electrodes were successively immersed in 0.05 M Co(CH₃COO)₂ aqueous solution, deionized water, 0.1 M NaOH aqueous solution and deionized water each for one minute to finish one cycle of the deposition. By repeating the above cycle for several times, the desired amount of Co(OH)₃ catalysts could be loaded on the surface of WO₃ electrodes.

Fig. S4 LSV curves of WO₃, WO₃/CoB and WO₃/FeB electrodes under AM 1.5G illumination or dark in 0.1 M Na₂SO₄ (pH 7).
Fig. S5 (a) and (b) LSV curves, (c) and (d) CA curves on the optimization of the loading amount of CoB, recorded under chopped AM 1.5G illumination in 0.1 M Na$_2$SO$_4$ (pH 7). In Fig. S5, the alteration of the loading amount of CoB below 20 μg does not show apparent influence on the photocurrent density. On the basis of cost-effective consideration, 2 μg is chosen for following use.

Fig. S6 (a) LSV curves and (b) CA curves on the optimization of the loading amount of FeB, recorded under chopped AM 1.5G illumination in 0.1 M Na$_2$SO$_4$ (pH 7). In Fig. S6, after the loading amount exceeds 4 μg, the alteration of catalyst amount does not show apparent influence on the photocurrent. On the basis of cost-effective consideration, 4 μg is chosen for following use.
Fig. S7 UV-vis absorption spectra of bare WO₃, WO₃/CoB and WO₃/FeB films.

Fig. S8 (a) PXRD pattern of obtained Co-Bi. (b) LSV curves on the optimization of the loading amount of Co-Bi, recorded under chopped AM 1.5G illumination in 0.1 M Na₂SO₄ (pH 7).

In Fig. S8a, the PXRD pattern of Co-Bi reveals that it formed in the amorphous phase, in accordance with the literature. In Fig. S8b, after exceeding the optimal loading amount 2 μg of Co-Bi, the photocurrent decreased.

Fig. S9 LSV curves on the optimization of the loading amount of Co(OH)ₓ, recorded under chopped AM 1.5G illumination in 0.1 M Na₂SO₄ (pH 7). By repeating the deposition for 2 cycles, the desired amount of Co(OH)ₓ catalyst is loaded on the surface of WO₃ electrode.
Fig. S10 Dark LSV curves of CoB and Co-B\textsubscript{i} electrodes recorded in 0.1 M Na\textsubscript{2}SO\textsubscript{4} (pH 7).

To compare the dark oxygen evolution reaction (OER) capacity of the CoB and Co-B\textsubscript{i}, 500 mg of the two catalysts were loaded on pure FTO substrates, respectively. After drying in vacuum, the dark LSV scans with the rate of 10 mV/s were performed. Both of the curves in Fig. S10 were recorded from the first scan. It is clear that apparent negative shift of the onset potential and obvious high current are obtained for the CoB electrode, indicating fast OER kinetics on the surface of CoB electrode in comparison with Co-B\textsubscript{i} electrode.

Fig. S11 CA curves of pristine WO\textsubscript{3}, WO\textsubscript{3}/CoB and WO\textsubscript{3}/FeB photoanodes, recorded under AM 1.5 G illumination in 0.1 M Na\textsubscript{2}SO\textsubscript{4} electrolyte (pH 7).

Fig. S12 EIS Nyquist plots with fitted curves of WO\textsubscript{3}, WO\textsubscript{3}/CoB and WO\textsubscript{3}/Co-B\textsubscript{i} and WO\textsubscript{3}/Co(OH)\textsubscript{x} photoanodes at a bias of 1 V\textsubscript{RHE} in 0.1 M Na\textsubscript{2}SO\textsubscript{4} electrolyte (pH 7) under AM 1.5G illumination.
Fig. S13 Bode phase plots of WO$_3$, WO$_3$/CoB and WO$_3$/FeB photoanodes, recorded in 0.1 M Na$_2$SO$_4$ electrolyte (pH 7) under AM 1.5G illumination. Compared to the pristine WO$_3$ photoanode, the characteristic peaks of modified photoanodes shift to lower frequency, revealing accelerated holes transport and prolonged holes lifetime. The lifetime of holes ($\tau$) can be extracted by the following equation:

$$\tau = \frac{1}{2\pi f_m}$$

The $\tau$ can be determined by the maximum phase peak in the frequency range ($f_m$) of bode plots. With respect to the $\tau$ of pristine WO$_3$ photoanode (24.76 ms), the WO$_3$/CoB and WO$_3$/FeB photoanodes display prolonged $\tau$ of 26.84 and 32.26 ms, respectively. It clearly suggests that integration of CoB and FeB catalysts with the WO$_3$ photoanodes is prone to facilitate holes transport and charge carrier separation, and thus promoting the photoelectrochemical (PEC) water oxidation.

Fig. S14 Electrochemical Mott-Schottky plots of WO$_3$, WO$_3$/CoB and WO$_3$/Co-B$_x$ and WO$_3$/Co(OH)$_x$ photoanodes at frequency of 10 Hz, recorded in 0.1 M Na$_2$SO$_4$ electrolyte (pH 7) under AM 1.5G illumination.

Table S1. Fitting results of resistance elements (R) from Nyquist plots for WO₃, WO₃/CoB and WO₃/FeB photoanodes.

<table>
<thead>
<tr>
<th></th>
<th>R₁ (Ω)</th>
<th>R₂ (Ω)</th>
<th>R₃ (Ω)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO₃</td>
<td>114.7</td>
<td>355.4</td>
<td>281.4</td>
</tr>
<tr>
<td>WO₃/CoB</td>
<td>116.3</td>
<td>290.2</td>
<td>166.8</td>
</tr>
<tr>
<td>WO₃/FeB</td>
<td>113.8</td>
<td>300.7</td>
<td>144.2</td>
</tr>
</tbody>
</table>

In Table S1, all photoanodes show similar R₁ at around 115 Ω. After coupling CoB and FeB, R₃ diminish apparently. Specifically, R₂ decrease from 355.4 to 290.2 and 300.7 Ω, and R₃ reduce from 281.4 to 166.8 and 144.2 Ω, for WO₃/CoB and WO₃/FeB, respectively. It implies that surface functionalization with CoB and FeB is capable to reduce the resistances for charge carrier transfer, and accelerate holes migration to OER.

Table S2. Fitting results of resistance elements (R) from Nyquist plots for WO₃, WO₃/CoB and WO₃/Co-B, and WO₃/Co(OH)ₓ photoanodes.

<table>
<thead>
<tr>
<th></th>
<th>R₁ (Ω)</th>
<th>R₂ (Ω)</th>
<th>R₃ (Ω)</th>
</tr>
</thead>
<tbody>
<tr>
<td>WO₃</td>

</tr>
<tr>
<td>WO₃/Co(OH)ₓ</td>
<td>116.0</td>
<td>426.5</td>
<td>257.3</td>
</tr>
</tbody>
</table>
In Table S2, all photoanodes show similar $R_1$. After coupling Co-B and Co(OH)$_x$, $R_3$ diminish while $R_2$ get increased, suggesting the loading of Co-B and Co(OH)$_x$ is mainly prone to mitigate the charge carriers recombination at the electrode/electrolyte interface. Specifically, $R_2$ upraise from 355.4 to 462.2 and 426.5 $\Omega$, and $R_3$ reduce from 281.4 to 241.3 and 257.3 $\Omega$, for WO$_3$/Co-B and WO$_3$/Co(OH)$_x$, respectively. Notably, WO$_3$ photoanode functionalized with CoB show drastically decreased $R_3$, if compared to the counterparts. Therefore, the WO$_3$/CoB photoanode exhibits higher PEC water oxidation capacity than the WO$_3$/Co-B and WO$_3$/Co(OH)$_x$ photoanodes (Fig. 2).
