1. Materials and methods

Reagents and deuterated solvents were commercially available and used without further purification except for β-cyclodextrin recrystallization three times. Compounds $1^S$, $2^S$, β-N3-CD$^{S3}$ were synthesized according to the literature procedures. NMR spectra were recorded on a Bruker Avance 500 MHz spectrometer. $^1$H and $^{13}$C NMR chemical shifts are reported relative to residual solvent signals. High-resolution mass data were obtained with an Agilent Technologies 6530 Accurat-Mass Q-TOF LC/MC instrument. The melting points were collected on a SHPSIC WRS-2 automatic melting point apparatus. UV-Vis experiments were conducted on a Perkin Elmer Lambda 750 UV/Vis spectrophotometer. The fluorescent experiments were conducted on a Hitachi F-7000 fluorescence spectrophotometer. Scanning electron microscopy (SEM) was performed on a Carl Zeiss Jena supra55 sapphire instrument. Transmission electron microscope (TEM) was performed on a Hitachi HT-7700 instrument. Atomic force microscope (AFM) was performed on an E-Sweep instrument. Dynamic light scattering experiments were performed using a Mastersizer 2000 Malvern Zetasizer. Rheological data were obtained using an ARES-G2 rheometer (Waters) with plate-plate geometry (diameter of 25 mm, gap is 200 μm). Oscillatory frequency sweep experiments were performed from 0.1 rad/s to 100 rad/s with a strain in the linear region at 20 °C. The scanning frequency of self-healing experiments were performed was 10 rad/s at 20 °C. Tensile tests were performed on an universal materials testing machine (Instron, model 5966) with a tensile speed of 10 mm/min at room temperature. Cuboid gel samples (30 mm long × 3.5 mm wide × 2.24 mm deep) were constructed in molds at 60 °C and then cooled to room temperature for testing machine.
