Supporting Information

Solventless Thermal Crosslinked Flexible Polymer Protective Layer for Highly Stable Lithium Metal Batteries.

Hyunjin Kim, Youn Sang Kim, and Jeeyoung Yoo*
Experimental section

Materials

Poly (ethylene glycol) dimethacrylate ($M_n$ 550, Sigma-Aldrich) was used as polymer film of protective layer. And tert-Butyl pivalate (Sigma-Aldrich) was employed as initiator of radical polymerization. Lithium (MTI Korea) was used as working, reference and counter electrode. The separator of polyethylene (20 $\mu$m) and electrolyte of 1 M LiPF$_6$ in EC (ethylene carbonate)/DEC (diethyl carbonate) (50/50 by volume, 50 mL) were obtained from Asahi Kasei Chemicals Corporation and PANAX ETEC Co. Ltd, respectively. LiFePO$_4$ (Hanwa Chemicals), PVdF (arkema) and Super P (MTI Korea) were employed as cathode material.

Preparation of PEGDMA protective layer

0.01 g of tert-Butyl pivalate was added into 1 g of poly (ethylene glycol) dimethacrylate. This solution was stirring at room temperature and dropped onto lithium metal surface. This droplet coated with the bar coater to make a film on the lithium metal surface. After casting process, polymerization of Poly (ethylene glycol) dimethacrylate was obtained for 1 minute with 100 °C on hot plate. Manufacturing processes of PEGDMA protective layer were performed in an argon-filled glove box.

Preparation of LiFePO$_4$ electrode

The cathode materials were prepared by mixing the LiFePO$_4$, super P and poly-(vinylidene fluoride) in a weight ratio of 8:1:1 in N-methyl pyrrolidone to ensure homogeneity. This slurry was coated on an Aluminum foil (18 um) and dried under the convection oven at 120 °C for 2 h and the vacuum oven at 120 °C for 12 h. Then the electrode foil was cut with 16 mm in
diameter. The loading density of this electrode is 1.8 mg cm^{-2}.

Electrochemical measurements

Coin cells (CR2032) were assembled to evaluate stability of Li metal surface after galvanostatic charge and discharge. All processes were carried out in an argon-filled glove box. In symmetrical cell test, Li metal is working electrode. Also, Li metal is counter and reference electrode. PE separator and 1M LiPF_6 in EC/DEC were used as separator and electrolyte, respectively. Cell tests were conducted with a current density of 1, 5 mA cm^{-2}. The charge and discharge time are 1 hour each. After cycle test is completed, the cell is opened with a scissor in a glove box, then washed with a few drops of diethyl carbonate (DEC) to measure SEM and XPS. To evaluate the rate capability, LFP/Li test was investigated. First cycle was performed with 0.1 C. Then, this cell was cycled in different C rates such as 0.2 C, 0.5 C, 1.0 C, 2.0 C, and 5.0 C respectively. Finally, 0.2c was performed to estimate the capacity recovery rate.
