1. General information

All solvents were distilled before use. Millipore water was obtained with a TKA MicroPure ultrapure water system. All other commercially available reagents were used as obtained unless otherwise specified. Reactions were monitored by TLC on silica gel plates (Macherey-Nagel POLYGRAM SIL G/UV254). Spots were visualized by UV light (254 nm and 366 nm). Reversed phase column chromatography was performed with an Armen Instrument Spot Flash Liquid Chromatography MPLC apparatus with RediSep C-18 Reversed Phase columns. Lyophilisation was done with a Christ Alpha 1-4 LD plus freeze dryer. The pH determination was performed with a pH-meter 766 Calimatic from Knick. The melting points were obtained with a Büchi Melting-Point B-540 apparatus with open end glass capillary tubes. The melting points are not corrected. The NMR spectra were measured with Bruker DMX 300, DRX 500 or AVHD 600 spectrometers. All measurements were recorded at room temperature using DMSO-d$_6$ as solvent. The chemical shifts are relative to the signals of DMSO-d$_6$ ($\delta^{1}H = 2.50$ ppm and $\delta^{13}C = 39.5$ ppm). The apparent coupling constants are given in Hertz (Hz). The description of the fine structure means: s = singlet, br. s = broad singlet, d = doublet, t = triplet, m = multiplet. The IR spectra were measured on a Varian 3100 FT-IR Excalibur Series.
2. Synthesis

The GCP binding motif E was synthesized starting from Boc-L-Dap(Boc)-OH B and the synthesis of the introduced GCP E is literature known.\textsuperscript{[1]} The synthesis of the AIE building block G was previously reported by us.\textsuperscript{[2]}

6. Transmission electron microscope (TEM)

Transmission electron microscope images were prepared by dropping the sample solution on a 400-mesh formvar copper grid coated with carbon. About 2 min after deposition the grid was tapped with filter paper to remove remaining solvent from the surface. Negative staining was performed by addition of a drop of an ethanol solution of uranyl onto the copper grid. After 1 min, the liquid on the surface of the grid was removed by tapping it with a filter paper.

7. Gelation Procedure

In a glass vial, a weighed amount of A was solved in DMSO (1 µL), than H2O (99 µL) was added to give a 10 mM stock solution of A (1% DMSO). The resulting stock solution (1 µL) was mixed with a 10 mM solution of malonic acid (2 µL), diluted with H2O (97 µL) and heated up to 70 °C. Storing the sample at room temperature leads to the gel formation after 7-8 days. The gel state was evaluated by the “stable to inversion of a test tube” method.

11. X-Ray Crystallography

The crystals were mounted on nylon loops in inert oil. Data were collected on a Bruker AXS D8 Kappa diffractometer with APEX2 detector (mono-chromated MoKα radiation, \( l = 0.71073 \, \text{Å} \)) at 100(2) K. The structures were solved by Direct Methods (SHELXS-97)\(^3\) and refined anisotropically by full-matrix least-squares on \( F^2 \) (SHELXL-2017)\(^4\),\(^5\). Absorption corrections were performed semi-empirically from equivalent reflections on basis of multi-scans (Bruker AXS APEX2). Hydrogen atoms were refined using a riding model or rigid methyl groups.
