Electronic Supplementary Information

Experimental section

Materials: Perylene-3,4,9,10-tetracarboxylic dianhydride (PTCDA, 97%), Nafion (5 wt%) solution, salicylic acid, sodium citrate, salicylate (C₇H₆O₃), sodium hypochlorite (NaClO), sodium nitroferricyanide (C₅FeN₆Na₂O), ammonium chloride (NH₄Cl), sodium hydroxide (NaOH), sodium sulfate (Na₂SO₄), carbon paper (CP; TGP-H-060), and para-(dimethylamino) benzaldehyde (C₉H₁₁NO) were purchased from Beijing Chemical Corporation. Hydrochloric acid (HCl) and ethanol were purchased from Aladdin Ltd. (Shanghai, China). All reagents were analytical reagent grade and used as received without further purification. Nafion 117 membrane (DuPont) was purchased from HESEN Co., Ltd. (Shanghai, China). Ultrapure water used throughout all experiments was purified through a Millipore system.

Preparation of PTCA-rGO: Graphene oxide (GO) was synthesized by a modified Hummer’s method and then calcinated in Ar at 700 °C with heating rate of 5 °C min⁻¹ for 1 h to obtain rGO. The perylene-3,4,9,10-tetracarboxylic acid (PTCA) was made by hydrolyzing PTCDA. Briefly, 0.1 g PTCDA was dissolved in an appropriate amount of 1.0 M NaOH. Then 1.0 M HCl was dropped gradually into the mixture solution and red deposits appeared in the yellow–green solution. Until precipitated completely, the prepared PTCA were collected by centrifugation, washed with ultrapure water and dried under vacuum at room temperature. 30 mg rGO and 30 mg PTCA dissolved in 30.0 mL water by ultrasonication, and then collected by centrifugation, washed with ultrapure water and dried under vacuum at 40 °C overnight.

Preparation of PTCA-rGO/CP: Carbon paper (CP) was cleaned via brief sonication with ethanol and water for several times. To prepare the PTCA-rGO ink, 5 mg PTCA-
rGO and 40 µL 5 wt% Nafion solution were dispersed in 960 µL water/ethanol (V : V = 1 : 3) followed by 3-h sonication to form a homogeneous ink. Then, 20 µL ink was loaded onto the CP (1 × 1 cm²) and dried under ambient condition. The PTCA-rGO/CP working electrode was prepared well.

**Characterizations:** TEM images were collected on a transmission electron microscopy (HITACHI H-8100, Tokyo, Japan). XPS measurements were performed on an ESCALABMK II X-ray photoelectron spectrometer using Mg as the exciting source. The absorbance data of spectrophotometer were acquired on SHIMADZU UV-1800 UV-Vis spectrophotometer. A gas chromatograph (SHIMADZU, GC-2014C) equipped with MolSieve 5A column and Ar carrier gas was used for H₂ quantifications. Gas-phase product was sampled every 600 s using a gas-tight syringe (Hamilton).

**Electrochemical measurements:** N₂ reduction experiments were carried out in a two-compartment cell under ambient condition, which was separated by Nafion 117 membrane. The membrane was protonated by first boiling in ultrapure water for 1 h and treating in H₂O₂ (5 wt%) aqueous solution at 80 °C for another 1 h, respectively. And then, the membrane was treaded in 0.5 M H₂SO₄ for 3 h at 80 °C and finally in water for 6 h. The electrochemical experiments were carried out with an electrochemical workstation (CHI 660E) using a three-electrode configuration with prepared electrodes, graphite rod and Ag/AgCl electrode (saturated KCl electrolyte) as working electrode, counter electrode and reference electrode, respectively. The potentials reported in this work were converted to reversible hydrogen electrode (RHE) scale via calibration with the following equation: E (vs. RHE) = E (vs. Ag/AgCl) + 0.059 × pH + 0.197 V and the presented current density was normalized to the
geometric surface area. For electrochemical N$_2$ reduction, chrono-amperometry tests were conducted in N$_2$-saturated 0.1 M HCl solution (30 mL).

**Determination of NH$_3$:** Concentration of produced NH$_3$ was spectrophotometrically determined by the indophenol blue method.$^1$ In detail, 2 mL of post-tested solution was got from the electrochemical reaction vessel. Then, 2 mL of 1 M NaOH solution (contains 5 wt% salicylic acid and 5 wt% sodium citrate) was followed by addition of 1 mL of 0.05 M sodium hypochlorite and 0.2 mL of sodium nitroferricyanide (1 wt%). After standing at 25 °C for 2 h, the UV-Vis absorption spectrum was measured. The concentration of indophenol blue was determined using the absorbance at wavelength of 655 nm. The concentration-absorbance curve was calibrated using the standard NH$_4$Cl solution with NH$_3$ concentrations of 0.0, 0.05, 0.10, 0.15, 0.20, 0.30, and 0.40 μg mL$^{-1}$ in 0.1 M HCl. Typically, 100 μg mL$^{-1}$ NH$_3$ solution was prepared (0.158 g NH$_4$Cl dissolved in 500 mL 0.1 M HCl) and diluted to 1 μg mL$^{-1}$. Then, 0.0, 0.1, 0.2, 0.3, 0.4, 0.6, and 0.8 mL NH$_3$ solution with concentration of 1 μg mL$^{-1}$ were poured into test tubes and separately diluted to 2 mL with 0.1 M HCl and the resulting concentrations of NH$_3$ in the solutions are 0.0, 0.05, 0.10, 0.15, 0.20, 0.30, and 0.40 μg mL$^{-1}$. The fitting curve ($y = 0.393 x + 0.043$, $R^2 = 0.999$) shows good linear relation of absorbance value with NH$_3$ concentration by three times independent calibrations.

**Determination of N$_2$H$_4$:** The N$_2$H$_4$ possibly was estimated by the method of Watt and Chrisp.$^2$ A mixed solution of 5.99 g C$_9$H$_{11}$NO, 30 mL concentrated HCl and 300 ml ethanol was used as a color reagent. Calibration curve was plotted as follow: firstly, preparing a series of N$_2$H$_4$ solutions of known concentration as standards; secondly, adding 5 mL color reagent to above N$_2$H$_4$ solution, separately, and standing 20 min at room temperature; finally, the absorbance of the resulting solution was measured at
460 nm. The fitting curve shows good linear relation of absorbance with N$_2$H$_4$·H$_2$O concentration (y = 0.881 x + 0.033, R$^2$ = 0.999) by three times independent calibrations.

*Determination of FE and NH$_3$ yield:* The FE for N$_2$ reduction was defined as the amount of electric charge used for synthesizing NH$_3$ divided the total charge passed through the electrodes during the electrolysis. The total amount of NH$_3$ produced was measured using colorimetric methods. Assuming three electrons were needed to produce one NH$_3$ molecule, the FE could be calculated as follows:

$$\text{FE (NH}_3\text{)} = 3 \times F \times [\text{NH}_3] \times V / (17 \times Q) \times 100\%$$

The rate of NH$_3$ formation was calculated using the following equation:

$$\text{NH}_3\text{ yield} = [\text{NH}_3] \times V / (m_{\text{cat.}} \times t)$$

The amount of NH$_3$ was calculated as follows:

$$m_{\text{NH}_3} = [\text{NH}_3] \times V$$

Where F is the Faraday constant, [NH$_3$] is the measured NH$_3$ concentration, V is the volume of the electrolyte in the cathodic chamber, Q is the total quantity of applied electricity, t is the reduction time, and m$_{\text{cat.}}$ is the loaded mass of catalyst on carbon paper.

The FE of H$_2$ was calculated as below:

$$\text{FE (H}_2\text{)} = 2 \times F \times V_{\text{H}_2} \times G \times p_0 / (R \times T \times Q) \times 100\%$$

Where $V_{\text{H}_2}$ is the volume concentration of H$_2$ in the exhaust gas from the electrochemical cell (GC data), G is the gas flow rate (mL min$^{-1}$), Q is the total quantity of applied electricity, $p_0 = 1.01 \times 10^5$ Pa, $T = 298.15$ K, and $R = 8.314$ J mol$^{-1}$ K$^{-1}$.

*Computational Details:* The density functional theory (DFT) calculations are performed using the projector augmented wave and generalized gradient
approximation in the form of the Perdew-Burke-Ernzerh of exchange-correlation functional,\textsuperscript{3,4} as implemented in the Vienna Ab Initio Simulation Package (VASP).\textsuperscript{5–7} The van der Waals interaction is described using the empirical correction scheme of Grimme. In our calculated slab models, an 8×8 two-dimensional graphene supercell with one carbon vacancy as a model of rGO has been used. One PTCA molecular is physically absorbed on the rGO surface. In DFT calculations, the energy cutoffs of plane wave for carbon, hydrogen, oxygen, and nitrogen are selected as 500 eV. A vacuum layer of 25 Å is added to avoid the interaction between nearby supercells. Then the structures are fully optimized until the following convergence criterions are reached: 10\textsuperscript{−4} eV for atomic energy and −0.02 eV Å\textsuperscript{−1} of atomic force. In NRR processes, the anode reaction i.e. H\textsubscript{2} ↔ 2(H\textsuperscript{+} + e\textsuperscript{−}) is taken as a convenient reference, which works as the source of proton and electrons. Six net proton coupled electron transfer steps (N\textsubscript{2} + 6H\textsuperscript{+} + 6e\textsuperscript{−} → NH\textsubscript{3}) are involved, There are several steps following associative mechanism where the nitrogen molecular are hydrogenated by protons (an asterisk,*, denotes a site on the surface).

\[
\begin{align*}
* + N\textsubscript{2}(g) & \rightarrow *N\textsubscript{2} \\

*NNH\textsubscript{2} + 4(H\textsuperscript{+} + e\textsuperscript{−}) & \rightarrow *N + NH\textsubscript{3} + 3(H\textsuperscript{+} + e\textsuperscript{−}) \\
*NHNH + 4(H\textsuperscript{+} + e\textsuperscript{−}) & \rightarrow *NHNH\textsubscript{2} + 3(H\textsuperscript{+} + e\textsuperscript{−}) \\
*N + 3(H\textsuperscript{+} + e\textsuperscript{−}) & \rightarrow *NH + 2(H\textsuperscript{+} + e\textsuperscript{−}) \\
*NH + 2(H\textsuperscript{+} + e\textsuperscript{−}) & \rightarrow *NH\textsubscript{2} + (H\textsuperscript{+} + e\textsuperscript{−}) \\
*NH\textsubscript{3} & \rightarrow NH\textsubscript{3} + *
\end{align*}
\]
Another dissociative mechanism, where the nitrogen molecules are first dissociated on the surface, is not discussed here because it hard to occur under our experimental temperature and pressure.

The Gibbs free energy change ($\Delta G$) of every elemental step is calculated by using the RHE model proposed by Nørskov et al.⁸ and they approximate the chemical potential of a proton-electron pair with a half of chemical potential of hydrogen molecule. The free energy change is defined as $\Delta G = \Delta E + \Delta ZPE - T\Delta S + \Delta G_U$, where $\Delta E$ is the reaction energy directly obtained from DFT calculations; $\Delta ZPE$ is the change in zero-point energy; $T$ is temperature (298.15 K); $\Delta S$ is the change in entropy. $\Delta G_U = -neU$, where $n$ is the number of electrons transferred and $U$ is the electrode potential. The zero-point energies and entropies of the NRR species are determined from the vibrational frequencies in which only the adsorbed species’ vibrational modes are computed explicitly and the electrocatalyst sheet is fixed. The entropies and vibrational frequencies of gas phase molecules are taken from the NIST database.⁹
