Experimental

Materials: The metallic Li foil (Φ15 mm) was obtained from China Energy Lithium Co., Ltd. The electrolyte composed of LiPF$_6$ (1.0 M) and EC/DMC (1:1 by volume) was purchased from DodoChem. Sulfonyl chloride (SO$_2$Cl$_2$) with purity of 99.5% was purchased from Macklin Co. Ltd.

Material characterization: The morphology and elemental distribution were observed by Field-emission scanning electron microscope (FE-SEM, Hitachi SU8010) with an energy dispersive X-ray spectrooscope (EDS, JEOL JSM-6100LV). All the batteries after cycled were disassembled and flushed with anhydrous dimethyl carbonate (DMC) solvent three times to remove remnant lithium salts, and then dried until the solvent volatilized thoroughly in glovebox before operating. The elemental valence of the SEI layer was detected by X-ray photoelectron spectroscopy (XPS, ESCALab220i-XL) with 300 W Al Kα radiations under ambient temperature.

Electrochemical measurements: Two-electrode cells configuration using standard 2032 coin-type cells were employed and assembled in an Ar-filed glove box with H$_2$O and O$_2$ concentrations below 0.1 ppm. The electrolytes were prepared by dissolving 0.5%, 1%, 2%, 5% SO$_2$Cl$_2$ additives (by quality) into 1.0 M LiPF$_6$ in EC/DMC. For the symmetric cell tests, two identical electrodes were carried out at various current densities under different electrolytes with the deposition capacity of 1 mAh cm$^{-2}$ or 4 mAh cm$^{-2}$ to investigate the lithium stripping/plating processes. The electrodes used in contrast experimental were pretreated the Li with SO$_2$Cl$_2$ for 5 minutes and tested at 1 mA cm$^{-2}$ under a fixed capacity of 1 mAh cm$^{-2}$. For the CE testing, 0.5 mAh cm$^{-2}$ of Li
without or with 2% $\text{SO}_2\text{Cl}_2$ additive was deposited on Cu foil ($\Phi 12 \text{ mm}$) and then stripped away up to 1.0 V at a current density of 0.5 mA cm$^{-2}$ for every cycle. Li$||$LiFePO$_4$ full cells tests used LiFePO$_4$ as the cathode at 1 C in a voltage range of 2.5-4.2V, the mass loading of the LiFePO$_4$ cathode material is about 5 mg cm$^{-2}$. EIS tests were carried out on an electrochemical workstation (CHI660a, Shanghai Chenhua) in the frequency ranging from $10^3$ to $10^{-2}$ Hz.
