S1. Experimental Procedures

2
Materials:
All reagents were purchased from Sigma-Aldrich and used without further purification unless otherwise stated.

Instrumental and Analytical Techniques:
Nuclear magnetic resonance (NMR) spectra were recorded using a Bruker Advance (III)-400 (\(^1\)H 400.130 MHz and \(^{13}\)C 100.613 MHz), Varian Inova-500 (\(^1\)H 500.130 MHz and \(^{13}\)C 125.758 MHz), Varian VNMRS-600 (\(^1\)H 600.130 MHz and \(^{13}\)C 150.903 MHz) or a Varian VNMRS-700 (\(^1\)H 700.130 MHz and \(^{13}\)C 176.048 MHz) spectrometer, at a constant temperature of 298 K unless otherwise stated. For variable-temperature (VT) measurements, operating temperatures were calibrated using an internal calibration solution of MeOH and glycerol. Chemical shifts (\(\delta\)) are reported in parts per million (ppm) relative to the signals corresponding to residual non-deuterated solvents [CD\(_2\)Cl\(_2\): \(\delta = 5.32\) or 54.00]. Coupling constants (\(J\)) are reported in Hertz (Hz). \(^{13}\)C NMR Experiments were proton-decoupled unless otherwise stated. Assignments of \(^1\)H and \(^{13}\)C NMR signals were accomplished by two-dimensional NMR spectroscopy (COSY, NOESY, HSQC, HMBC). NMR spectra were processed using MestReNova version 11. Data are reported as follows: chemical shift; multiplicity; coupling constants; integral and assignment. Low-resolution mass spectrometry (MS) were performed using a Waters Xevo QTOF equipped with an Atmospheric Solids Analysis Probe (ASAP). High-resolution ASAP (HR-ASAP) mass spectra were measured using a Waters LCT Premier XE high resolution, accurate mass UPLC ES MS (also with ASAP ion source). Elemental analysis data were obtained on a EuroEA Elemental Analyser. TGA was performed on a Metter TGA/SDTA851e/LF/1100 apparatus at a heating rate of 20 °C/min under a nitrogen atmosphere. DSC measurements were done on a DSC Q 100 TA Instrument at a heating rate of 10 °C/min under a nitrogen atmosphere. Melting points (M.P.) of the prepared compounds were estimated using Electrothermal Melt-Temp apparatus. Cyclic voltammetry (CV) measurements were carried out with a glassy carbon working electrode in a three-electrode cell using a \(\mu\)-Autolab Type III (EcoChemic, Netherlands) potentiostat. Platinum wire and Ag/AgNO\(_3\) (0.01 mol/L in acetonitrile) were used as counter and reference electrodes, respectively, and Bu\(_4\)NBF\(_6\) in dichloromethane (0.1 M) was used as electrolyte. The data were collected using GPES (General Purpose Electrochemical System) software. Electrochemical measurements were conducted at room temperature at a potential rate of 100 mV/s. The reference electrode was calibrated versus ferrocene/ferrocenium redox couple. The solid-state ionisation potential energy (\(I_p^{CV}\)) was estimated from the onset oxidation potential by using the relationship \(I_p^{CV} = 4.8 + E_{ox}\), where the potential is related to that of ferrocenium/ferrocene. The electron affinity (\(EA^{CV}\)) values were obtained from the reduction potential using the approximation \(EA^{CV} = 4.8 + E_{red}\). The theoretical calculations were carried out using the Gaussian 09 quantum chemical package.\(^1\) Full geometry optimisations of the compounds in their electronic ground state were performed with density functional theory method (DFT)\(^2\) using the BMK\(^3\) functional with the 6-31G(d) basis set in vacuum. The excited-state properties of the molecules were calculated by the means of time-dependent DFT (TD-DFT)\(^4\)–\(^6\) and TDA-DFT\(^7\)\(^8\) calculations employing 6-31G(d) basis set in vacuum. The amount of charge (\(q\)) transferred from donor to acceptor in the excited state was calculated using the methodology reported elsewhere.\(^9\) The orbital compositional analysis was performed with Multiwfn software.\(^10\) Steady-state absorbance measurements were
conducted using a UV-3600 Shimadzu spectrophotometer and photoluminescence measurements were conducted using a Jobin Yvon Horiba Fluoromax 3. Emission spectra were calibrated for detector efficiency using company supplied instrument specific calibration files. Time-resolved photophysical measurements have been described elsewhere.\textsuperscript{11} The excitation source for all temperature-dependent/time-resolved measurements was a nitrogen laser (337 nm) ((LTB-MNL 100, Lasertechnik Berlin) with spectra obtained on a gated intensified charge-coupled device (iCCD) camera (Stanford Computer Optics) at differing delay times. Power-dependent measurements were performed using the same laser source with delayed emission intensity measured as a function of laser fluence between ~0.2-80 µJ. Solid-state samples were prepared on clean quartz substrates prepared as a 1% w/w ratio in Zeonex\textsuperscript{®} or a 10% w/w ratio in DPEPO, dropcast from toluene on a hotplate until dry. PLQYs were measured using a calibrated Horiba Quanta-Φ integrating sphere coupled to a Fluorolog3 spectrometer using 380 nm excitation. Data was processed using the included Fluoracle software. The X-ray single-crystal diffraction data for \textit{meta-2} and \textit{para-3} were collected at 120.0(2) K using $\lambda$MoK$\alpha$ radiation ($\lambda = 0.71073$ Å) on a Bruker D8Venture (Photon100 CMOS detector, $\mu$S-microsource, focusing mirrors) diffractometer and for compound \textit{ortho-1} on an Agilent XCalibur (Sapphire-3 CCD detector, fine-focus sealed tube, graphite monochromator) diffractometer, both equipped with a Cryostream (Oxford Cryosystems) open-flow nitrogen cryostats. All structures were solved by direct method and refined by full-matrix least squares on $F^2$ for all data using Olex2\textsuperscript{12} and SHELXT\textsuperscript{13} software. All non-hydrogen atoms were refined anisotropically, hydrogen atoms were placed into calculated positions and refined in riding mode. Crystal data and parameters of refinement are listed in Table S1. Crystallographic data for the structure have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication CCDC 1917139–1917141.
S2. Synthetic Procedures

**General procedure for diazotiation-iodination reaction**<sup>14</sup>

The corresponding amine (2.00 g, 16.9 mmol) in 20 mL of acetone was treated with 10 mL of concentrated HCl at room temperature. The solution was cooled to 0 °C and treated dropwise with NaNO<sub>2</sub> (1.51 g, 22.0 mmol) dissolved in 5 mL of water. The solution was stirred at 0 °C for 2 h and then treated with KI (8.41 g, 50.7 mmol) in 15 mL of water. After 6 h, the solution was quenched with 100 mL of the saturated aqueous solution of Na<sub>2</sub>SO<sub>3</sub> and extracted with diethyl ether (3 × 170 mL). The combined organic extracts were washed with brine (100 mL), dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered, and the solvent was removed under reduced pressure. The crude residue was purified by flash column chromatography using a 1:9 ratio of ethyl acetate/hexanes to give the desired iodide.

2-Iodobenzonitrile (S1a) M.P. 53 – 55 °C (lit.<sup>15</sup> 54 – 55 °C), 3-iodobenzonitrile (S1b) M.P. 40 – 42 °C (lit.<sup>16</sup> 39 – 40 °C) and 4-iodobenzonitrile (S1c) M.P. 121 – 123 °C (lit.<sup>16</sup> 122 – 124 °C) were prepared according the literature procedures.<sup>16,17</sup>

**General procedure for Buchwald-Hartwig amination reaction**<sup>18,17</sup>

2,7-Di-<em>tert</em>-butyl-9,9-dimethyl-9,10-dihydroacridine (1.00 g, 3.11 mmol) and the corresponding iodobenzonitrile (0.78 g, 3.42 mmol) were placed in a dry Schlenk reactor and the flask was deaerated then 10 mL of anhydrous toluene was added under an argon atmosphere. t-BuONa (0.89 g, 9.33 mmol) was added and reaction mixture was deaerated. 1,1’-Bis(diphenylphosphino)ferrocene (dppf) (0.17 g, 0.31 mmol) and Pd(OAc)<sub>2</sub> (0.07 g, 0.31 mmol) were then added. The reaction mixture was deaerated again and heated to 115 °C. After 24 h, the reaction mixture was cooled to the room temperature, diluted with water and extracted with ethyl acetate (3 × 100 mL). The combined organic extracts was dried over Na<sub>2</sub>SO<sub>4</sub> and the solvent was removed under reduced pressure. The crude residue was purified by silica gel column chromatography, using a 5:1 ratio of hexanes and toluene. The solvent was evaporated and the residue was recrystallised from a 1:4 dichloromethane and isopropanol mixture to yield the desired product.

2-(2,7-Di-<em>tert</em>-butyl-9,9-dimethylacridin-10(9H)-yl)benzonitrile (orth-1)

![Image of molecular structure](Image)

The title compound was obtained from S1a (0.78 g, 3.42 mmol) as off-white crystals (0.87 g, 2.06 mmol, 66%). M.P. 238 – 240 °C (DSC 242 °C). <sup>1</sup>H NMR (600 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 7.96 (dd, <em>J</em> = 7.8, 1.5 Hz, H<sub>2</sub>), 7.90 (td, <em>J</em> = 7.8, 1.6 Hz, H<sub>6</sub>), 7.68 (td, <em>J</em> = 7.7, 1.2 Hz, H<sub>5</sub>), 7.49 (dd, <em>J</em> = 8.0, 1.1 Hz, H<sub>1</sub>, H<sub>6</sub>), 7.47 (d, <em>J</em> = 2.2 Hz, 2H, H<sub>14a</sub>), 6.97 (dd, <em>J</em> = 8.6, 2.3 Hz, 2H, H<sub>10</sub>), 5.98 (d, <em>J</em> = 8.5 Hz, 2H, H<sub>6</sub>), 1.75 (s, 6H, H<sub>17</sub>), 1.36 (s, 8H, H<sub>13</sub>), 1.35 (s, 8H, H<sub>11</sub>). <sup>13</sup>C NMR (151 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 145.2 (C<sub>2</sub> or C<sub>1</sub>), 144.1 (C<sub>11</sub>), 138.2 (C<sub>8</sub>), 135.6 (C<sub>3</sub>), 135.2 (C<sub>4</sub>), 134.0
(C₆), 130.2 (C₁₅), 129.2 (C₅), 124.1 (C₁₀), 123.0 (C₁₄), 117.3 (C₇), 116.3 (C₂ or C₁), 113.4 (C₉), 37.0 (C₁₆), 34.6 (C₁₂), 32.1 (C₁₇ and C₁₃). Elemental analysis found: C, 85.28; H, 8.13; N, 6.59 %; molecular formula C₃₀H₃₄N₂ requires: C, 85.26; H, 8.11; N, 6.63 %. HRMS-ASAP, m/z calculated for C₃₀H₃₄N₂ [M⁺] 423.2756, found 423.2787.

3-(2,7-Di-tert-butyl-9,9-dimethylacridin-10(9H)-yl)benzonitrile (meta-2)

The title compound was obtained from S1b (0.78 g, 3.42 mmol) as colourless crystals (1.06 g, 2.51 mmol, 81%). M.P. 183 – 195 °C (DSC 198 °C). ¹H NMR (700 MHz, CD₂Cl₂) δ 7.79 (dt, J = 7.8, 1.5 Hz, 1H, H₄), 7.78 – 7.75 (m, 1H, H₅), 7.63 – 7.62 (m, 1H, H₃), 7.61 (dt, J = 7.5, 1.7 Hz, 1H, H₆), 7.42 (d, J = 2.3 Hz, 2H, H₁₄), 6.96 (dd, J = 8.6, 2.3 Hz, 2H, H₁₀), 6.08 (d, J = 8.6 Hz, 2H, H₉), 1.72 (s, 6H, H₁₇), 1.35 (s, 18H, H₁₃). ¹³C NMR (176 MHz, CD₂Cl₂) δ 144.0 (C₁₁), 143.7 (C₂ or C₁), 138.6 (C₈), 136.5 (C₆), 135.5 (C₃), 132.2 (C₅), 131.6 (C₄), 130.4 (C₁₃), 124.1 (C₁₀), 122.9 (C₁₄), 117.8 (C₂ or C₁), 116.2 (C₇), 114.4 (C₉), 36.9 (C₁₆), 34.6 (C₁₂), 32.3 (C₁₇), 32.2 (C₁₃). Elemental analysis found: C, 85.29; H, 8.09; N, 6.62 %; molecular formula C₃₀H₃₄N₂ requires: C, 85.26; H, 8.11; N, 6.63 %. HRMS-ASAP, m/z calculated for C₃₀H₃₄N₂ [M⁺] 423.2756, found 423.2786.

4-(2,7-Di-tert-butyl-9,9-dimethylacridin-10(9H)-yl)benzonitrile (para-3)

The title compound was obtained from S1c (0.78 g, 3.42 mmol) as colourless crystals (0.98 g, 2.32 mmol, 75%). M.P. 286 – 288 °C (DSC 290 °C). ¹H NMR (700 MHz, CD₂Cl₂) δ 7.84 – 7.81 (m, 2H, H₃), 7.48 – 7.45 (m, 2H, H₄), 7.44 (d, J = 2.3 Hz, 2H, H₁₂), 7.02 (dd, J = 8.5, 2.3 Hz, 2H, H₈), 6.35 (d, J = 8.5 Hz, 2H, H₇), 1.68 (s, 6H, H₁₅), 1.35 (s, 18H, H₁₁). ¹³C NMR (176 MHz, CD₂Cl₂) δ 146.7 (C₂ or C₁), 144.3 (C₅), 137.9 (C₆), 134.4 (C₃), 132.2 (C₁₃), 128.9 (C₄), 123.4 (C₈), 122.2 (C₁₂), 118.0 (C₂ or C₁), 115.8 (C₇), 110.3 (C₃), 36.7 (C₁₄), 34.2 (C₁₀), 31.6 (C₁₁), 30.9 (C₁₃). Elemental analysis found: C, 85.31; H, 8.12; N, 6.57 %; molecular formula C₃₀H₃₄N₂ requires: C, 85.26; H, 8.11; N, 6.63 %. HRMS-ASAP, m/z calculated for C₃₀H₃₄N₂ [M⁺] 423.2756, found 423.2800.
S3. $^1$H and $^{13}$C Spectroscopic Characterisation of Synthesised Compounds

Figure S3.5. $^1$H NMR of para-3
Figure S3.4. $^{13}$C NMR of *para*-3.
S4. Variable-Temperature NMR

We performed VT NMR measurements on ortho-1, meta-2, para-3 to determine if we could measure the energy barriers to exchange of the methyl group environments due to rotation around the hindered C–N bond connecting the acridine to the benzonitrile fragment. Only the ortho-1 isomer showed an exchange process that reached slow exchange regime in the accessible temperature range (from room temperature down to –98 °C). VT 1H NMR spectra were acquired to facilitate analysis using a two-spin system model in the WinDNMR19 software package. In order to obtain a solution of ortho-1 with a low freezing point (5.7 mg in 0.8 mL) for 1H NMR analysis, a mixture of CS₂ (0.6 mL) with CD₂Cl₂ (0.2 mL) was used as solvent. A series of spectra ranging from 24 °C to –98 °C were recorded (Figure S4.1).

![13C NMR spectra](image)

**Figure S4.1.** Partial 1H VT NMR spectra of ortho-1. Peaks corresponding to the methyl group environments X/X' are observed as averaged signals in the fast exchange regime, but appear as individual distinct signals at low temperature in the slow exchange regime.

Analysis of the 1H NMR spectra reveals that, within the temperature range studied, signals corresponding to the methyl groups broaden, merge into the baseline, and then re-emerge as two separate peaks as the temperature is decreased. We selected six spectra for further analysis, choosing temperatures close to the transition from the fast to the slow exchange regimes (Figure S4.2). Lineshape analysis was performed to derive rate constants by comparison to model spectra produced using WinDNMR.
Figure S4.2. $^1$H VT NMR spectra of ortho-1 used for lineshape analysis. The dashed blue lines illustrate the resolution of single peaks into pairs of peaks as temperature decreases.

Activation energy barriers for the rotation of the methyl groups were calculated (Table S4.1) for each of the five temperatures using equation S4.1:

$$\Delta G^\ddagger = -RT \ln \frac{k_r h}{k_B T}$$

Equation S4.1. A variation of the Eyring equation, where $k_r$ is the measured rate constant, $k_B$ is the Boltzmann constant, $T$ is temperature, $h$ is Planck’s constant, and $R$ is the ideal gas constant.

Table S4.1. Calculated activation energies ($\Delta G^\ddagger$) for the rotation of the methyl groups.

A line was fitted (Figure S4.3) to a plot of $\Delta G^\ddagger$ vs $T$. The slope of the line corresponds to $-\Delta S^\ddagger$ and the y-axis intercept to $\Delta H^\ddagger$. The entropy of activation $\Delta S^\ddagger$ was calculated to be 66.2 J mol$^{-1}$ K$^{-1}$ and enthalpy of activation $\Delta H^\ddagger$ was calculated to be 62.5 kJ mol$^{-1}$. 
Figure S4.3. A plot of the experimentally measured free energy of activation $\Delta G^\ddagger$ for rotation of ortho-1 as a function of temperature.

As we did not observe slow exchange for meta-2 and para-3 down to temperatures as low as $-98 \, ^\circ\text{C}$, we can estimate that $\Delta G^\ddagger$ of the ring rotation must be <33 kJ mol$^{-1}$, making the assumption that the limiting chemical shifts of the methyl groups would be similar to those observed for ortho-1.

S6. Analysis of Crystal Packing

In order to discern if the differences in the planarity of the acridine ring systems shown in Figures S5.1–S3.3 arise because of specific crystal packing phenomena, we performed calculations to model the Hirshfeld surfaces of ortho-1, meta-2, and para-3 and to estimate the interaction energies between molecules in the crystals.

Hirshfeld surfaces\(^2\) give insights into the interactions between molecules in the crystal lattices. We calculated Hirshfeld surfaces for the crystal packing structures in CrystalExplorer\(^{17,20} \) using an iso-value of 0.5 and mapping the normalised contact distance, \(d_{norm}\). The surfaces highlight (Figures S6.1, S6.3 and S6.5) in red any regions in which the molecular surfaces meet at distances shorter than the sum of van der Waals radii, while white and blue illustrate regions where they meet at distances that are the sum of the van der Waals radii or longer, respectively. Overall, the Hirshfeld surfaces reveal there are only a few contacts that are slightly shorter than the sum of van der Waals radii – there are only a small number of red patches, which are faint in colour and small in size. This data suggests that there are no strong and specific noncovalent interactions in the solid state that direct the crystal packing. The most significant close contact found was an intermolecular C≡N···H–C interaction present in the lattice of para-3.

We performed DFT calculations to quantify the interaction energies between neighbouring molecules in the solid state using the CE-B3LYP [B3LYP/6-31G(d,p)] energy model in CrystalExplorer\(^{17,20} \). Based on the X-ray crystal structure coordinates, a cluster was generated around a central molecule, extending to molecules that come within 3.8 Å of the central molecule at any point. As each of the crystal structures of ortho-1, meta-2, and para-3 have only one unique molecule in each of the unit cells (\(Z' = 1\)), all of the surrounding molecules are related to the central molecule by a symmetry operation (labelled ‘Symmetry Op.’ in Tables S6.1, S6.2 and S6.3). These energy calculations allow us to elucidate the total interaction energies (\(E_{tot}\), in kJ·mol\(^{-1}\)) between neighbouring molecules, based on the individual components for electrostatic (\(E_{ele}\)), polarization (\(E_{pol}\)), dispersion (\(E_{dis}\)), and repulsion (\(E_{rep}\)) energies. In each of the Tables below, \(N\) indicates the number of molecules of a particular symmetry operation included in the cluster. \(R\) is the distance between the molecular centroids (mean atomic position) of the central molecule and the molecule generated by the given symmetry operation. A colour code is given for each table entry, which matches the colouring of the relevant molecules in the corresponding cluster diagrams, Figures S6.2, S6.4 and S6.6.
Figure S6.1. A Hirshfeld surface analysis of ortho-1, viewed along the crystallographic (b) $a$-axis, (c) $b$-axis, and (d) $c$-axis, shows a lack of significant close contacts.

Table S6.1. Calculated intermolecular interaction energies (in kJ·mol$^{-1}$) for the solid-state structure of ortho-1.
