Fig. S1. (a) Origin of the chirality within the smectic phases of bent-core molecules.[4] Owing to the bend shape each molecule possesses a dipole moment in the molecular plane and perpendicular to the long axis of the molecules. Layer normal, tilt direction and the polar axis define either a right handed coordinate system (+), whereas in the mirror image these vectors define a left handed system (-). Changing either polarisation direction or tilt direction changes the chirality sense of the layer (indicated by blue/red colour). Changing both, polarisation direction and tilt direction retains the chirality sense.

3. Experimental Methods
The mesophase behaviour of all the compounds was examined under a polarized light optical microscope (Optiphot-2, Nikon) attached with a hot stage (FP-82 HT, Mettler) by sandwiching the sample between a glass slide and a cover-slip. The transition temperatures and the associated enthalpies were obtained from thermograms recorded on a Perkin-Elmer DSC-7, differential scanning calorimeter. The cooling and heating rates were 10 °C min⁻¹. The electro-optical switching characteristics were examined with a home-built setup for electrooptical investigations using ITO cells as specified (EHC Japan). The triangular-wave method was used for determination of the P_s-values by integration of the peak areas. Optical investigation of the switching process was made in the same setup under a polarizing light optical microscope.
microscope between crossed polarizers using a DC field or a low frequency (<1 Hz) triangular wave field.

Powder X-ray diffraction measurements were carried out with a Guinier film camera (Huber) with samples in glass capillaries (1 mm) in a temperature-controlled heating stage using quartz-monochromatized CuKα radiation (1.54 Å; 30 to 60 min exposure time, calibration with the powder pattern of Pb(NO₃)₂). 2D patterns for aligned samples on a glass plate on a temperature controlled heating stage (alignment at the sample – glass or at the sample – air interface) were recorded with a 2D detector (HI-STAR, Siemens).

\[N,N'-\text{Bis}(4\text{-ethoxycarbonylphenyl})-N,N'-\text{alkyleneureas 2/0}\]

Under an argon atmosphere, a mixture of ethyl 4-bromobenzoate (19.2 g, 84 mmol), Cs₂CO₃ (27.3 g, 84 mmol), Pd₂(dba)₃ (366 mg, 0.5 mol-%) and Xanthphos® (36 mg, 1.5 mol-%) are suspended in dry dioxane (100 ml) and heated under reflux for 30 hours. After cooling to room temperature CH₂Cl₂ (75 ml) is added and the mixture is filtered. The solvent of the filtrate is evaporated and the residue is crystallized twice from MeOH. In case of compound 2/0 the residue contains most of the product. The residue is treated with diluted hydrochloric acid and the mixture is filtered again. The residue is combined with the filtrate from the first filtration. The solvent is evaporated and the residue is suspended in hot MeOH (50 ml) and filtered. The residue is crystallized from CHCl₃.
