General Details
All chemicals were purchased from Sigma-Aldrich and were used without further purification. All solvents used were HPLC grade. Chloroform-d (CDCl₃, >99.9%) and methanol-d₄ (MeOD, >99.7%) were purchased from Euriso-top and stored at 4°C.

The recorded Rf values were determined by Thin Layer Chromatography (TLC) using 0.2 mm silica gel 60 F₂₅₄ pre-coated aluminium sheets, commercially available from Merck. Visualisation was determined by UV at 254nm or, in the case of amine intermediates, by staining with a ninhydrin solution. Column chromatography was carried out using silica gel 60, 35 to 70 micron particles, commercially available from FluoroChem. Solvent ratios are described where appropriate.

¹H NMR spectra were recorded using a Bruker DPX 300 or Bruker DRX 500 instrument. ¹³C Nuclear Magnetic Resonance were recorded at 75 MHz or 125 MHz using a Bruker DPX 300 instrument or Bruker DRX 500 instrument. ¹H spectra are referenced to tetramethylsilane and chemical shifts given in parts per million downfield from TMS. Coupling constants are reported to the nearest 0.1 Hz. ¹H NOESY Spectroscopy was carried out using the standard Bruker noesygtp-X program with the following parameters: sample concentration 60 mM, 2048 (F2).1024(F1) data points in TPPI mode with Z gradients, relaxation delay 1.77s, 40 scans per increment, sweep width 4529 Hz in both directions and 1.2s mixing time.

Melting points were determined using a Griffin D5 variable temperature apparatus and are uncorrected. Microanalyses were obtained on a Carlo Erba Elemental Analyser MOD 1106 instrument, found composition is reported to the nearest 0.05%. Infrared spectra were recorded on a Perkin-Elmer FTIR spectrometer and samples analysed as solids. Mass spectra were obtained using a micrOTOF spectrometer using time-of-flight electro-spray analysis. Positive or negative ion detection is specified.
Synthesis of Cyclic Trimers

Reductive amination

To a stirred solution of primary amine (1 eq.) and aldehyde (≥1 eq.) in methanol, under an atmosphere of nitrogen, was added borane-pyridine (small excess). The reaction mixture was stirred at 35 °C for 12-36 h, until TLC indicated reaction completion. Concentration and direct purification by column chromatography gave target material which was dried under vacuum and fully characterised.

(Note: borane-picoline – a white solid with greater stability and reactivity than borane-pyridine can be also be used for this reaction)

Amide coupling

To a stirred solution of secondary amine (1 eq.) and acid (1 eq.) in chloroform, under an atmosphere of nitrogen, was added dichlorotriphenylphosphorane (2.4 eq.). The reaction mixture was heated at reflux (65°C) for 24-36 h, until TLC indicated no further reaction. Concentration and direct purification by column chromatography isolated target material which was dried under vacuum and fully characterised.
Hydrogenation

To a stirred solution of nitro compound (1 eq.) in anhydrous methanol, under an atmosphere of nitrogen, was added palladium on charcoal catalyst (10% w/w). The nitrogen atmosphere was flushed out under vacuum and hydrogen gas introduced via a balloon (2L, excess). The mixture was stirred at room temperature for 6-24 h, until TLC indicated no further reaction. The mixture was passed through a pad of celite, concentrated and the isolated product dried under vacuum. Purification of the target amine was achieved by recrystallisation or chromatography where appropriate.
