Compound 4 (2.9 g, 4.78 \times 10^{-3} \text{ mole}) in methylene chloride (120 mL) and trifluoroacetic acid (60 mL) was stirred one hour at room temperature then concentrated under vacuum. The crude product was diluted in methylene chloride, washed with aqueous sodium hydroxide (5 %). Aqueous phase was washed with methylene chloride (twice) and acidified by chlorhydric acid. The white precipitate was filtered, washed with water and dried under vacuum. Pure product was obtained as white crystals and used without other purification (1.926, yield 92 %), melting point 113 °C (pasty). Anal. Compound 8 (200 mg, 0.14 mmol) was added after 5 minutes to a solution of 10,15,20-triphenyl porphyrin-5-para-benzoic acid (46 mg, 7 × 10⁻³ mol) containing HOBT (14.6 mg, 0.105 mmol), EDC (20 mg, 0.105 mmol) and Et₃N (45 μL) in dry methylene chloride (20 mL) under argon. The solution was stirred overnight under argon at room temperature. The crude mixture was washed with aqueous chlorhydric acid (10%), water, aqueous sodium hydrogenarbonate (10%) and water then dried on sodium sulfate and filtered. The solution was concentrated under vacuum. The pure compound 10 was obtained by preparative thin layer chromatography (silica gel, methylene chloride/acetone, 1/1, v/v) and crystallization from a mixture of methylene chloride/heptane (red powder, yield 74%). Preparation and characterization of liposomes

A homemade auto-recording Langmuir-type film trough coupled to a R&K Wilhelmy device (Riegler and Kirstein, GmbH, Germany) was used to record compression isotherms of monolayers of the porphyrin derivatives and mixtures with DMPC, spread from a chloroform/methanol (9:1) solution onto the aqueous subphase (160 cm²). After the deposition of the studied solution, the solvents were allowed to evaporate for 15 min before the beginning of compression (1 cm/min). All experiments were run at 22±1°C, and the results are mean values of at least three measurements. The experimental uncertainty was estimated to be 0.2 mN/m. Ultrapure water (γ = 72.4 mN/m at 22°C) produced by a Millipore Synergy 185 apparatus coupled with a RiOs5™, with a resistivity of 18.2 MΩ/cm. was used in all experiments.

A 10 mM HEPES (N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid, Sigma, Saint-Louis, USA) buffer solution containing 1mM CaCl₂, 2H₂O and 1mM NiCl₂, 6H₂O (VWR International, West Chester, USA), was used for liposome preparation. The pH was adjusted to 6.5 by addition of NaOH 1M (Merck, Darmstadt, Germany). Concanavalin A (Type IV) was purchased from Sigma (Saint-Louis, USA).

Liposomes were formed by solvent evaporation from DMPC-porphyrin mixed solutions (500:1) in chloroform-methanol (9:1), hydration of the resulting dry lipid film, and then extrusion of vesicles ten times through polycarbonate membranes of 200 nm pores.
diameter, using an extruder (Whitley, Lipex). The size of the obtained multilamellar vesicles was measured by the Zetasizer Nano-ZS90 (Malvern).
