Experimental Section

In a typical procedure to prepare Fe$_2$O$_3$ with high surface area, 0.33ml of 0.36 mol·L$^{-1}$ Al(H$_2$PO$_4$)$_3$ aqueous solution (Fluka) was added to 15.1 ml of 2.33 mol·L$^{-1}$ Fe(NO$_3$)$_3$ solution (Sigma-Aldrich). The mixture was then placed in an oven and heated to 380°C with a heating rate of 4 °C·min$^{-1}$. After 1 hour, the brown powder was collected in a 10 ml bottle and cooled down to room temperature. Finally, 3.04 g of product was obtained.

To synthesize Fe$_2$O$_3$ with high, reproducible BET surface area without addition of Al(H$_2$PO$_4$)$_3$, 0.25 mol·L$^{-1}$ Na$_2$CO$_3$ aqueous solution was added dropwise to 100 ml of 0.1 mol·L$^{-1}$ Fe(NO$_3$)$_3$ solution under stirring at 80 °C, until the pH value reached 8.2. After filtration and drying, the precipitate was calcined at 350°C for 6 h.

In a typical procedure to synthesize MgAl$_2$O$_4$ with high surface area, 2.54 mL of 3.83 mol·L$^{-1}$ Mg(NO$_3$)$_2$ aqueous solution was mixed with 7.98 mL 2.43 mol·L$^{-1}$ Al(NO$_3$)$_3$ aqueous solution and 6.7 mL of 4.41 mol·L$^{-1}$ citric acid aqueous solution. 6.7 g of carob
tree cernel flour was then added to the mixture to form a gel. The gel was then transferred to an oven and heated up to 550 °C at a heating rate of 4 °C·min⁻¹. After remaining at this temperature for 1 hour, 1.43 g of the MgAl₂O₄ product with amorphous structure and a BET surface area of 175 m²·g⁻¹ was obtained.

In a typical procedure to synthesize MgO with high surface area, 6 g of corn starch was added to 9 mL of 3.83 mol·L⁻¹ Mg(NO₃)₂ aqueous solution under stirring. The mixture was then transferred to an oven and heated up to 550 °C at a heating rate of 4 °C·min⁻¹. After remaining at this temperature for 1 hour, 1.41 g of the MgAl₂O₄ product with periclase structure and a BET surface area of 155 m²·g⁻¹ was obtained.

The conversion of glycerol to allyl alcohol was carried out in a stainless steel fixed bed reactor (7 mm inner diameter). In a typical reaction, 150 mg of Fe₂O₃ was mixed with 2 g of quartz (both sieved, 250-500 μm) and put into the tube reactor. After the temperature of the reactor had reached 320 °C, a 35 wt% glycerol aqueous solution was pumped in at a flow rate of 1 mL·h⁻¹ using a syringe pump (Pharmacia Fine Chemicals P-500). Nitrogen with a flow rate of 15 mL·min⁻¹ was used as carrier gas and after 1 hour, the products were collected hourly in ethanol cooled by an ice-water trap. The samples were analyzed with a HP 5890 Series II gas chromatograph equipped with a DB-WAXetr column (J&W, bonded and cross-linked polyethylenglycol, 0.25 mm inner diameter, 15 m long) and an FID detector. Butanetriol was selected as the internal standard for the quantification of glycerol and 1-propanol was selected as the internal standard for the quantification of acrolein and allyl alcohol. Since 1-propanol could also be a product of the full hydrogenation of acrolein, all samples were also checked without standard and no 1-propanol was detected in all cases. For reactions between acrolein and different alcohols, acrolein was premixed with the corresponding alcohol at a molar ratio of 1:1, all
mixtures were pumped through the reactor under the same conditions. Since crotonaldehyde and cinnamaldehyde have low solubilities in both glycerol and water, glycerol solution and the aldehyde were pumped using two individual pumps to the same line with 2 meters dipped in a supersonic bath to form a “homogeneous” mixture before entering the reactor. Butanetriol works as internal standard for cinnamaldehyde and cinnamylalcohol, and 2-butanol for crotonaldehyde and crotylalcohol.
BET surface area was measured by nitrogen adsorption on an ASAP 2010 adsorption analyzer (Micromeritics). X-ray diffraction patterns were recorded with a Stoe Stadi P diffractometer. TEM images were obtained with a Hitachi H-7500 microscope. Thermogravimetric analysis was performed on a NETZSCH STA 449C thermobalance.

Carbon balance

Figure S1. gives an original GC spectrum of a representative product. As introduced in the manuscript, quantitative analysis was carried out for glycerol, allyl alcohol, hydroxyacetone and acrolein, which typically add up to 50–60% of the total carbon balance. However, if one simply adds the area of all the other unquantified peaks to the quantitative values, 90.36–98.33% of the total carbon balance can be reached, which indicates that the total carbon balance is actually in an acceptable range. However, the composition of the unknown compounds is extremely complicated. For example, in the spectrum shown in Fig. S1, more than 60 peaks other than the known products are detected as well. The identification of these compounds is unfortunately impossible.
