Table of the contents:
1. **Fig. S1** IR spectrum of 1, page S2.
2. **Fig. S2** A space-filling model showing the arrangement of molecular “loops” intercalated by one molecular “string” (left), and the unusual intercalated fashion of two “strings” in one “loops” (right), page S2.
3. **Fig. S3** A schematic presentation of the molecular “string” (a), molecular “string” (b), the arrangement of molecular “loops” intercalated by one molecular “string” (c), and the unusual intercalated fashion of two “strings” in one “loop” (d), page S2.
4. **Fig. S4** A schematic illustration of detailed entangled fashion in the MORF, page S3.
5. **Fig. S5** Schematic view of the topology of 3D MORF, page S3.
6. **Fig. S6** A space-filling model showing the arrangement of the [PW12O40]3− clusters in the tunnels B/C (a) and A (b); View of the 1D tunnels along [011] direction (c). Guest water molecules are omitted for clarity, page S4.
7. **Fig. S7** Output of a calculated X-ray powder patterns by POWDER CELL, page S4.
8. **Fig. S8** TG curve of 1, page S5.
9. **Fig. S9** left) Cyclic voltammograms of the 1-CPE in the 1 M H2SO4 solution at different scan rates (from inner to outer: 60, 80, 100, 120, 140, 160, and 180 mV·s−1) and right) The dependence of anodic peak II current on scan rates, page S5.
Fig. S1 IR spectrum of 1.

Fig. S2 A space-filling model showing the arrangement of molecular “loops” intercalated by one molecular “string” (left), and the unusual intercalated fashion of two “strings” in one “loops” (right).

Fig. S3 A schematic presentation of the molecular “string” (a), molecular “string” (b), the arrangement of molecular “loops” intercalated by one molecular “string” (c), and the unusual intercalated fashion of two “strings” in one “loop” (d).
**Fig. S4** A schematic illustration of detailed entangled fashion in the MORF.

**Fig. S5** Schematic view of the topology of 3D MORF: 2-fold interpenetrated dia nets of Class Ia related by a single translation (a), the enlarged view of the interpenetration mode (b) and the entanglement of the two “strings” in one “loops” to shrink to a 4-connected node of the dia net (c).
Fig. S6 A space-filling model showing the arrangement of the [PW₁₂O₄₀]³⁻ clusters in the tunnels B/C (a) and A (b); View of the 1D tunnels along [011] direction (c). Guest water molecules are omitted for clarity.

Fig. S7 Output of a calculated X-ray powder patterns by POWDER CELL.
Fig. S8 TG curve of I.

Fig. S9 Cyclic voltammograms of the I-CPE vs Ag/AgCl obtained at different scan rates (from inner to outer: 60, 80, 100, 120, 140, 160, and 180 mV·s$^{-1}$) in the 1 M H$_2$SO$_4$ solution (up) and the dependence of anodic peak current of III on scan rates (low).
Discussion

1 Structural feature of compound 1.

Polypseudo-rotaxane is a particular species of entangle system with the character that the “loops” are threaded by “strings”, in which there are no hopf-links, no closed circuits are linked to other closed circuits.¹ The compounds with polypseudo-rotaxane structures have attracted more and more attentions due to their attractive structural features and potential applications. For example, Loeb et al. reported the first examples of charge neutral, metal organic polypseudo-rotaxane frameworks (MORFs) which were synthesized by the combination of a disulfonated-dibenzo-24crown-8 ether wheel and a dicationic 1,2-bis(pyrindinium)ethane axle.² By introducing the flexible btx ligand into the molybdate system under the hydrothermal conditions, Xu and Dong obtained two compounds, [Ag(btx)]₄[SiMo₁₂O₄₀]·2H₂O and [Cu(btx)]₄[SiMo₁₂O₄₀], which respectively showed 0D + 1D and 1D + 2D polypseudo-rotaxane motifs.³ We isolated the first polypseudo-rotaxane structure based on the Wells-Dawson polyoxometalate.⁴ Very recently, Stoddart and coworkers have constructed polypseudo-rotaxanes by choosing diverse mechanically bonded macromolecules and well discussed them in a tutorial review.⁵

In comparison with the examples mentioned above, compound 1 has three structure features. (a) The entangled fashion: in compound 1, one “loop” encircles two “strings” rather than the common single one. (b) The unique POM-encapsulated porous MORF structure: Compound 1 represents the first example of POM-encapsulated MORF with well-defined 1D nano-scale tunnels bringing together the structure features of POMs, rotaxanes and PCPs. (c) The high dimension structure: usually, the dimension of the MORF structures are 1D or 2D, whereas compound 1 possesses the 3D MORF structure with a surprised topology of 2-fold ⁶ dia nets of the Class Ia.⁶

The topological analysis of the MORF has been performed by reducing the entanglement of the two “strings” in one “loops” illustrated in Fig. S2, right, to a 4-connected node, that is, shrinking the macrocycle/loop to a point, resulting in a node...
with 4 arms/strings pointing out in 4 directions. Surprisingly, the analysis of the topology of MORF, according to a recent classification, reveals that it belongs to Class Ia (the two identical interpenetrated dia nets are generated only by translation and the translating vector is [100] (14.17 A)) (Fig. S5)’’.

2 Analyses of BVS, IR and TG measurements.

In compound 1, all W atoms are in +VI oxidation state obtained by bond valence sum (BVS) calculations. The copper atoms are all in +I oxidation state, confirmed by coordination environments, BVS calculations, and red color of the crystalline. The oxidation state of Cu center was changed from +II to +I in the preparation process, which is often observed in the hydrothermal reaction systems containing both N-donor of organic ligands and CuII ions. Since 1 was isolated from acidic aqueous solution, one proton is attached to PW12 cluster to compensate charge balance, which is similar to the case of [Ag2(3atrz)2][HPMoVI10MoV2O40].9

In the IR spectrum (see Fig. S1), the peaks at of at 808, 896, 981 and 1078 cm⁻¹ are attributed to ν(P–Oc), ν(W=Oδ), νas(W–Oδ–W) and νas(W–Oc–W) vibrations of α-Keggin cluster, respectively. The bands at 1231–1643 cm⁻¹ region are assigned to characteristic peaks of the bimb lignds. Additionally, the band at 3428 cm⁻¹ is ascribed to characteristic peak for water molecules.

The TG curve of 1, which was performed in air to explore its thermal stability, exhibits two weight loss steps (Fig. S8). The first weight loss step of 1.6% (calc. 1.47%) below 250 °C corresponds to the loss of water molecules. The second weight loss step of 17.7% (calc. 18.76%) occurred in the range of 250–533 °C is ascribed to the decomposition of organic bimb molecules and collapse of Keggin PW12 clusters. The total weight loss is 19.3%, in consistence with the calculated value of 20.2% and also supporting the chemical composition of 1.

3 The CVs of 1-CPE.

The CVs of 1-CPE show three reversible redox processes in the potential range -800 to 400 mV. The mid-point potentials, $E_{1/2} = (E_{pa} + E_{pc})/2$, for the three processes are -216, -467 and -691 mV, respectively. The reduction processes (II’ and III’)

Supplementary Material (ESI) for Chemical Communications
This journal is (c) The Royal Society of Chemistry 2010
correspond to two consecutive one-electron reduction of W centers, while IV’ corresponds to a two-electron process. On the reverse scan, the irreversible anodic peak I observed at the peak potential of 186 mV is assigned to the oxidation of copper (I). The linear dependence of anodic peak current of III on scan rates indicates possible surface-controlled process.
