General Procedures:
All reactions were carried out in oven- or flame-dried glassware under an atmosphere of dry nitrogen unless otherwise noted. Except as otherwise indicated, all reactions were magnetically stirred and monitored by analytical thin layer chromatography (TLC) using Whatman pre-coated silica gel flexible plates (0.25 mm) with F254 indicator or Merck pre-coated silica gel plates with F254 indicator. Visualization was accomplished by UV light (254 nm), with combination of potassium permanganate and/or phosphomolybdic acid solution as an indicator. Flash column chromatography was performed according to the method of Still using silica gel 60 (mesh 230-400) supplied by Silicycle. Yields refer to chromatographically and spectrographically pure compounds, unless otherwise noted.

Commercial grade reagents and solvents were used without further purification except as indicated below. Toluene (anhydrous, 99.8 %, 18 L in Pure-Pac™), dichloromethane (anhydrous, 99.9%, 18L in Pure-Pac™), hexanes (anhydrous, 99.9%, 18L in Pure-Pac™), and THF (anhydrous, 99.9%, 18L in Pure-Pac™) purchased from Aldrich were purified by M. BRAUN solvent purification system (A2 Alumina).

1H NMR, 13C NMR and 31P NMR spectra were recorded on a Bruker Avance 500 (500 MHz 1H, 125 MHz 13C, 202 MHz 31P). Tetramethylsilane was used as an internal standard for 1H NMR (δ: 0.0 ppm), CDCl 3 and H 3PO 4 for 13C NMR (δ: 77.0 ppm) and 31P NMR (δ: 0.0 ppm) as external standards, respectively. The proton spectra are reported as follows δ (position of proton, multiplicity, coupling constant J, number of protons). Multiplicities are indicated by s (singlet), d (doublet), t (triplet), q (quartet), p (quintet), h (septet), m (multiplet) and br (broad). High-performance liquid chromatography (HPLC) was performed on a Varian ProStar Series equipped with a variable wavelength detector using chiral stationary columns (0.46 cm x 25 cm) from Daicel. Optical rotations were measured on a JASCO DIP-1000 digital polarimeter.

1. Synthesis of racemic 2-aryl substituted cyclic ketones (rac-2a-i)

\(^a\) Isolated yield after column chromatography separation. \(^b\) Enantiomeric excess (ee) was determined by HPLC analysis using chiral OD-H column.

Various other metal triflates were investigated as Lewis acid activators with (S)-HOP in the presence of superstochiometric amount of isopropanol. Although all the metal triflates provide the protonation product in quantitative yield, enantioselectivity highly depended on the choice of metal triflates. Yb(OTf)\(_3\) and Eu(OTf)\(_3\) provided the protonation product...
in 23 and 20 % ee, respectively, whereas Sc(OTf)3, In(OTf)3, Zn(OTf)2, and Cu(OTf)2 provided only the racemic product. Among the metal triflates tested, La(OTf)3 gave the best result in terms of enantioselectivity.
2) Screening of Ligand

Utilizing La(OTf)₃ as a Lewis acid activator, next we investigated various other ligands. The ligands without phosphinyl group, although a chiral ligand has acidic protons, afforded the protonation product with no enantioselectivity (entries 2 and 3). These results imply that the importance of the phosphoryl moiety to achieve enantioselectivity presumably because this moiety provides rigid conformation to the LBA. Furthermore, when (S)-Me-HOP was used in place of (S)-HOP, no enantioselectivity was obtained, which implies the importance of OH group in the asymmetric protonation reaction (entry 4). The oxidized (S)-HOP, (S)-Ox-HOP, provided the protonation product only in moderate enantioselectivity (entry 5). From these results suggested two important findings: 1) phosphoryl group is needed to induce stereoselectivity in asymmetric protonation reaction, 2) the protonation reaction with the alcohol activated by La(OTf)₃ may be less or non enantioselective pathway regardless of the structure of chiral ligands.

With these optimized conditions, next we moved our attention to the optimization of ligand structure. Enantioselectivity showed strong dependence on electronic and steric effect of substituents on the phosphorous atom in (S)-HOP. Ligand bearing diethylphosphorous moiety showed much lower enantioselectivity (entry 2). Electron-rich aromatic substituent has a little deleterious effect on the enantioselectivity (entry 5). Ligands bearing bulky aromatic substituents displayed much lower selectivities (entries 3-4). Among the ligands examined, simple phenyl substituted (S)-HOP gave the best result in terms of enantioselectivity (entry 1).
Next, solvents was further optimized in protonation reaction. Interestingly, the reactivity of LBA in the protonation reaction displayed a strong dependence of the solvent; the protonation reaction was significantly slow in coordinating solvents, such as ether and THF, whereas the protonation reaction is much faster in non-coordinating halogenated solvents, such as CH$_2$Cl$_2$ (entries 1-3). Although CH$_2$Cl$_2$ and Et$_2$O provided the protonation product in the similar levels of enantioselectivities (entries 1 and 2), CH$_2$Cl$_2$ was chosen as the optimal solvent because the reactivity of LBA significantly increased in non-coordinating halogenated solvent than coordinating solvent.

6) Asymmetric protonation reaction under an argon atmosphere

however, even in the standard conditions, sometimes the enantioselectivity was fluctuated from 40 to 74 % ee. We assumed that this inconsistancy in enantioselectivity might result from the oxidation of the chiral Brønsted acid to the corresponding phosphine oxide ligand ((S)-Ox-HOP) during the protonation reaction. Indeed, the reaction mixture providing low enantioselectivity has a new peak at 30 ppm in $^{31}$P NMR, which is corresponding to the oxidized (S)-HOP. Furthermore, the protonation reaction with LBA from (S)-Ox-HOP gave the the protonation product with similar enantioselectivity (eq 1). The inconsistancy in enantioselectivity might result from less selective protonation with the LBA from the oxidized (S)-HOP ligand. Thus, this might be avoided by by preventing (S)-HOP from oxidizing into (S)-Ox-HOP. To our delight, when the protonation reaction was carried out under an argon atmosphere, the desired product was obtained with 75 % ee without any inconstitancy.

3-2 Substrate Scope

**General Procedure:** La(OTf)$_3$ (5.8 mg; 0.10 mmol; 0.050 eq) and (S)-HOP (10 mg; 0.22 mmol; 0.11 eq) were added to a flame dried test tube. The reaction flask was charged with an argon and then CH$_2$Cl$_2$ (2 mL) and MeOH (64 mg; 2.0 mmol; 10.0 eq) were added to the reaction mixture at room temperature. The reaction mixture was stirred for 30 min at room temperature. Silyl enol ether of 2-aryl cyclohexanone (0.20 mmol; 1.0 eq) was added dropwise to the reaction mixture at room temperature and the reaction was monitored by TLC. When all the silyl enol ether was completely consumed, the reaction mixture was quenched with NaHCO$_3$ (aq), and extracted with ether. The organic layer was collected, dried over Na$_2$SO$_4$, and concentrated. Column chromatography on silica (15 % ethyl acetate in hexanes) gave the desired product. Enantiomeric ratio (er) was determined by HPLC analysis with a chiral column.
