General Experimental

All reactions were carried out under Ar in flame-dried glassware unless otherwise mentioned. The solvents used were purified by distillation over the drying agents indicated and were transferred under Ar: THF (Na), CH₂Cl₂ (P₂O₁₀), Et₃N (CaH₂), toluene (Na). Anhydrous ClCH₂CH₂Cl was purchased from Aldrich or freshly distilled (CaH₂). Asynt DrySin heating blocks on stirrer hotplates were employed for reactions with temperature controlled via external probe.

Flash chromatography: Fluorochem silica gel 60 (43-63 µm). Thin layer chromatography (TLC): Macherey Nagel silica gel 60F₃₄ analytical plates (plastic support) which were developed using standard visualizing agents: UV fluorescence (254 and 366 nm), phosphomolybdic acid /Δ, and potassium permanganate /Δ. IR: Perkin–Elmer Spectrum 100 FTIR spectrometer, only selected absorbencies (υmax) are reported in cm⁻¹. MS and HRMS (EI): VG ProSpec or VG-ZabSpec at 70 eV. High resolution EI spectra were measured using perfluorokerosene (PFK) as an internal calibrant. MS and HRMS (ES): Micromass LCT using a methanol mobile phase. HRMS was obtained using a lock-mass to adjust the calibrated mass scale. MS data are reported as m/z (relative intensity). Commercially available compounds were purchased from Aldrich, Fluka, Acros, Strem or Alfa Aesar and used without further purification. Commercial pyridine N-oxide was dissolved in CH₂Cl₂ and dried over Na₂SO₄. The solution was filtered and solvent removed under reduced pressure to afford a white powder which was stored under Argon. NMR: Spectra were recorded on Bruker AC300 (¹H = 300 MHz, ¹³C = 75.5 MHz), Bruker AV300 (¹H = 300 MHz, ¹³C = 75.5 MHz), Bruker AV400 (¹H = 400 MHz, ¹³C = 101 MHz), and Bruker DRX500 (¹H = 500 MHz, ¹³C = 126 MHz) in the solvents indicated; Chemical shifts (δ) are given in ppm relative to TMS. The solvent signals were used as references and the chemical shifts converted to the TMS scale (CDCl₃: δC = 77.0 ppm; residual CHCl₃ in CDCl₃: δH = 7.26 ppm. Coupling constants (J) are reported in Hz. Multiplicity is denoted in ¹H NMR by: s (singlet), d (doublet), t (triplet), q (quadruplet), m (multiplet). 1D ¹³C NMR spectra were recorded using the PENDANT pulse sequence from the Bruker standard pulse program library. 2D spectra were recorded using the following pulse sequences from the Bruker standard pulse program library: PENDANT, DEPT 45, DEPT 135; Gradient COSY 90; Gradient HSQC for J(C,H) = 145 Hz; Gradient HMBC for correlations via J(C,H).

Formation of ynamides

All ynamides were prepared according to the method of Stahl using the following procedure.⁹

General procedure 1 (GP1)

CuCl₂ (0.2 eq), amide (5 eq) and Na₂CO₃ (2 eq) were added to a flame-dried 500 mL three-necked round-bottomed flask. The flask was purged with oxygen for 15 min and a solution of pyridine (2 eq) in dry toluene (0.1 M) was added. A balloon filled with oxygen was connected to the flask and the stirred mixture was heated at 70 °C. After 15 min, a solution of alkyne (1 eq) in dry toluene was added by syringe pump over 4 h. The mixture was allowed to stir at 70 °C for another 4 h and was then cooled to rt. The reaction mixture was concentrated under reduced pressure and the residue was purified by flash chromatography.

Catalysis optimisation study

An array of gold(I) and gold(III) species proved to be active for this process (Table S1, Entries 1-8), whilst platinum(II) salts, Brønsted acids and an electrophilic bromine source gave no reaction and/or degradation (Entries 9-13). The reaction proceeds well in a variety of solvents showing moderate \( (E)\)-selectivity (Entries 14-19). Use of acetonitrile, diethyl ether and acetone gave lower yields (<50%) Other nucleophilic oxidants were explored (diphenylsulfoxide, tempo, picolinic acid, substituted pyridine and triethyl oxides) with poor results.

Products of Catalysis

2-Oxo-N-2-diphenyl-N-tosylacetamide 2a

The catalyst system was prepared by addition of CH2Cl2 (1 mL) to AuClPPh3 (5 mg, 0.01 mmol) and AgOTs (4 mg, 0.01 mmol). After stirring for 10 min at RT, a white precipitate of AgCl was observed and ynamide 1a (34.7 mg, 0.1 mmol) and pyridine-N-oxide (22 mg, 0.22 mmol) were added. The reaction mixture was stirred at rt until complete consumption of the starting material before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure and the residue purified by flash chromatography [hexanes:EtOAc (20:1)] to give oxoacetamide 2a (30 mg, 79%) as a colourless oil; 1H-NMR (300 MHz, CDCl3): δ = 7.90-7.88 (m, 2H), 7.75 (d, J 8.4, 2H), 7.70-7.60 (m, 1H), 7.55-7.50 (m, 2H), 7.44-7.33 (m, 5H), 7.13 (d, J 6.9, 2H), 2.48 (s, 3H); 13C-NMR (101 MHz, CDCl3): δ = 187.6, 166.7, 145.9, 134.6, 134.1, 133.5, 132.7, 130.6 (2C), 130.2, 129.8 (2C), 129.6 (2C), 129.5 (2C), 129.1 (2C), 128.9 (2C), 21.8; IR (neat): ν = 2921, 2988, 1685, 1672, 1595, 1487, 1449, 1374, 1325, 1299, 1191, 1148, 1086, 1073, 1034, 955, 912, 758, 737, 710, 694, 662; HR-MS (ES-TOF): m/z: calcd for C21H17NO4NaS: 402.0776, found 402.0765 [M+Na].

Catalytic oxidative reactions: General procedure 2

System A (GP2A)

A solution of the corresponding ynamide (0.3 mmol, 1 eq) in ClCH2CH2Cl (1.5 mL) was added to a mixture of dichloro(2-pyridinecarboxylato)gold (5.9 mg, 0.015 mmol, 5 mol%) and pyridine-N-oxide (32 mg, 0.34 mmol, 1.1 eq). The reaction mixture was stirred at 70 °C until complete consumption of the starting material was observed before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure and purification of the residue was performed by flash chromatography.

System B (GP2B)

A solution of the corresponding ynamide (0.3 mmol, 1 eq) in THF (1.5 mL) was added to a mixture of goldtribromide (6.6 mg, 0.015 mmol, 5 mol%) and pyridine-N-oxide (32 mg, 0.34 mmol, 1.1 eq). The reaction mixture was stirred at rt until complete consumption of the starting material was observed before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure and purification of the residue was performed by flash chromatography.

In many cases, co-elution of starting material and a product limits our ability to precisely determine the reaction time. In these cases reactions were left for an extended period of time (20 h) to ensure complete conversion which highlights the mildness of the reaction system.

**Comments on structure analysis:**

NOE experiments were performed to assign \(E/Z\) configurations in cases where ambiguous \(J\) values are observed between the vinylic protons or when the product contains a quaternary vinylic carbon.

In the case of enimide (E)-3h, a NOE contact is evident between the vinylic proton at 7.81 ppm and the methyl protons at 3.75 ppm. No NOE contacts were observed between the vinylic protons or between the vinylic protons at 6.69 and the methyl protons at 3.75 ppm.

In the case of enimide (E)-9b, a NOE contact is evident between the vinylic proton at 6.43 ppm and the methyl protons at 3.67 ppm. No NOE contacts were observed between the vinylic proton and the proton at 1.82-3.67 ppm, or between the vinylic proton and the methylene protons at 1.81-1.59 ppm or 1.53-1.06 ppm.

**Control Reactions on the isomerization of 9b**

*Test n°1*: A solution of (Z)-9b (35 mg, 0.1 mmol, 1 eq) in ClCH\(_2\)CH\(_2\)Cl (0.5 mL) was added to a mixture of dichloro(2-pyridinecarboxylato)gold (2 mg, 0.005 mmol, 5 mol%) and pyridine-N-oxide (11 mg, 0.12 mmol, 1.2 eq). The reaction mixture was stirred at 70 °C for 20 h before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure. Analysis of the crude mixture showed 9b (E:Z 21.9:1).

*Test n°2*: A mixture of dichloro(2-pyridinecarboxylato)gold (1 mg, 2.5 μmol, 5 mol%) and pyridine-N-oxide (6 mg, 0.06 mmol, 1.2 eq) were added to a solution of 9b (E:Z 1:5.4) (18 mg,0.05 mmol, 1 eq) in ClCH\(_2\)CH\(_2\)Cl (0.3 mL). The reaction mixture was stirred at room temperature for 8 h before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure. Analysis of the crude mixture showed 9b (E:Z 2.5:1).

*Test n°3*: Pyridine-N-oxide (6 mg, 0.06 mmol, 1.2 eq) was added to a solution of 9b (E:Z 1:5.4) (18 mg, 0.05 mmol, 1 eq) in ClCH\(_2\)CH\(_2\)Cl (0.3 mL). The reaction mixture was stirred at 70 °C for 8 h before being filtered through a pad of silica. The filtrate was then concentrated under reduced pressure. Analysis of the crude mixture showed 9b (E:Z 9.5:1).

These control reactions show that (Z)-9b is readily converted into the thermodynamic product (E)-9b. While we should not set-aside stereoelectronic rationalisation, in particular the role of solvent on preferred conformation, the
discrepancy in the results observed between 8a and 3h under the same reaction conditions (System A, i.e. for 3h only the (E)-isomer is observed whereas for 8a significant amounts of (Z)-isomer are observed), show that the benzyl appendage on the oxazolidinone unit in 8a plays a leading role in determining the nature of the kinetic product. We can initially rationalise the impact of the benzyl appendage for the formation of (Z)-9b as the major isomer on purely steric grounds if we consider the reactive conformations for 1,2-insertion (I and II). Under System B, which is seen to favour the potential isolation of kinetic products [as a result of slower isomerisation to the thermodynamic products than observed with System A]: if Y is large (e.g. 4-benzyloxazolidin-2-one of 8b) conformer II is preferred to minimise unfavourable steric interactions between Y and the β-substituents, thus affording (Z)-9b as the kinetic product. Further studies to identify the control factors for E/Z selectivity will be pursued in due course.
