General Remarks

All the reagents were obtained from commercial suppliers and used as received unless otherwise noted. Aqueous solutions were prepared from distilled water. The organic solutions from all liquid extractions were dried over anhydrous Na₂SO₄ for a minimum of 15 minutes before filtration. Reactions were monitored by thin-layer chromatography (TLC) on silica gel precoated glass plates (0.25 mm thickness, 60F-254, E. Merck). Flash column chromatography was performed using pre-coated 0.2 mm silica plates from Selecto Scientific. Chemical yields refer to pure isolated substances. Melting points were obtained either using Büchi Melting Point-B540. Mass spectra were obtained using the Instrumentation includes Finnigan MAT95XL-T and Micromass VG7035. ¹H NMR and ¹³C NMR spectra were recorded on Bruker ACF-300 (300 MHz) or AVF500 spectrometers (500 MHz). In addition, key compounds were characterized by X-ray Diffraction. The solvent signal of CDCl₃ was referenced at δ = 7.26. Coupling constants (J values) are reported in Hertz (Hz). ¹H NMR data are recorded in the order: chemical shift value, multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; br, broad), number of protons that gave rise to the signal and coupling constant, where applicable. ¹³C spectra are proton-decoupled and recorded on Bruker ACF300 (300 MHz) and ACF500 spectrometers (500 MHz). The solvent, CDCl₃, was referenced at δ = 77 ppm and d₆-DMSO was referenced at δ = 39.5. CDCl₃ (99.8%-Deuterated) and d₆-DMSO (99.8%-Deuterated) was purchased from Aldrich and used without further purification.

Melting points were obtained either using Büchi Melting Point-B540.

\textbf{Figure S1.} \textsuperscript{1}H NMR spectra (5.0 mM, CDCl\textsubscript{3}, 500 MHz) of circular pentamer 1. (a) and (b) were recorded at 223 K; (c) and (d) were recorded at 298 K. 1 in (a) and (c) was made by the stepwise construction reported by us previously (\textit{Org. Lett.} \textbf{2008}, \textit{10}, 5127) while 1 in (b) and (d) was made by one-step cyclization reaction as reported in this work. These comparisons show that 1 made by two different routes are identical.
Figure S2. $^1$H NMR spectra of pentamers 1-7 (500 MHz, 50% CDCl$_3$/50% DMSO-d$_6$, 298K). The $^1$H NMR spectra of 1 and 6 in CDCl$_3$ showed four sets of proton signals corresponding to the aromatic and amide protons. Similarly, two sets of aromatic protons and one set of amide protons were observed for 2-5 and 7. The observation of these single sets of $^1$H NMR signals is in accord with the highly symmetrical nature of 1-7. In particular, the amide protons of 1-7, resonating at the very low field (> 10 ppm over a concentration range of 1-20 mM), are a diagnostic indicator of the presence of strong H-bonding interactions, consisting of both S(5) and S(6) type intramolecular H-bonds that cause the rigidification of the amide linkages and a circularly folded aromatic backbone in 1-7. S refers to the solvent signal from CDCl$_3$.

**Ab Initio Molecular Modeling:** All the calculations were carried out by utilizing the Gaussian03 program package. The geometry optimizations were performed at the density functional theory (DFT) level, and the Becke’s three parameter hybrid functional with the Lee-Yang-Parr correlation functional (B3LYP) method was employed to do the calculations. The 6-31G* basis from the Gaussian basis set library has been used in all the calculations. All the trimers and hexamers were relaxed fully without any symmetry constraints. The harmonic vibrational frequencies and zero-point energy corrections were calculated at the same level of theory. Single point energy were obtained at the B3LYP level in conjunction with the 6-311+G (2d,p) basis set with use of the above optimized geometries, i.e., B3LYP/6-311+G (2d,p) //B3LYP/6-31G (d).

*a* Density functional theory at the B3LYP/6-31G* level with the single point energy calculated at the level of B3LYP/6-311+G**.

*b* The relative energy per repeating unit from entries 1-4 anis normalized against pentamer 1, respectively.

**Figure S8.** Top and side views of *ab initio*-optimized structures of circularly folded (a) tetramer, (b) pentamer 1, (c) hexamer and (d) heptamer in acetonitrile at the B3LYP/6-31G* level. The computationally derived relative energy per repeating unit among these circular foldamers is normalized based on pentamer 1 in acetonitrile. The computationally derived planar backbone and geometry in 1 are nearly identical to those found in the crystal structure. For clarity of view, all the interior methyl groups in (a)-(d) were removed.
Figure S9. Both (a) and (b) show the top and side views of ab initio-optimized structure of circular pentamer 6, carrying five ethoxy groups in its interior. For comparison, shown in (c) are the top and side views of circular pentamer 1 that contains five smaller methoxy groups in its interior. It can be seen that the backbone in 6 is much more distorted than that in 1. In (b), the interior ethyl groups were removed for clarity of view.

Experimental Conditions for Amide Hydrogen-Deuterium Exchange Experiments

Solutions of circular pentamers 1-7 (2.0 or 0.20 mM) were prepared by dissolving the compounds into 50% DMSO-d$_6$ in CDCl$_3$ (total volume: 0.95 mL) and the spectra were recorded at room temperature as the reference spectra at $t = 0$. The H-D exchange experiment was initiated by adding 0.05 mL of D$_2$O into the samples, which resulted in a solution in a mixed solvent of D$_2$O/DMSO-d$_6$/CDCl$_3$ (2:19:19 v/v). The resultant spectra were then recorded (500 MHz) at appropriate time intervals, based on which the time-dependent peak areas of the amide protons were obtained and fitted into the pseudo-first-order reaction rate equation of $(I_t - I_\infty) / (I_0 - I_\infty) = e^{-kt}$, where $I_0$, $I_\infty$, and $I_t$ correspond to the integrated area of the corresponding proton at $t = t$, $t = \infty$, and $t = 0$; $k$ is the decay rate constant. The half-life $T_{1/2}$ is related to $k$ by $T_{1/2} = \ln 2/k$. Thus, the half-life $T_{1/2}$ was obtained by fitting the time-dependent peak areas into the above equation [$(I_t - I_\infty) / (I_0 - I_\infty) = e^{-kt}$] with Origin 7.7 program.
