General information

Commercially available reagents and solvents were used without further purification. $^1$H NMR, $^{19}$F NMR and $^{13}$C NMR spectra were recorded on a Varian 500 MHz NMR spectrometer. $^1$H NMR spectra were referenced to tetramethylsilane ($\delta$, 0.00 ppm) using CDCl$_3$ as solvent. $^{13}$C NMR spectra were referenced to solvent carbon (77.23 ppm for CDCl$_3$). $^{19}$F NMR spectra were referenced to 2% perfluorobenzene (s, -164.9 ppm) in CDCl$_3$ or 5% trifluoroacetic acid (s, -76.55 ppm) in D$_2$O. PBS or human sera were used as NMR solvents. A capillary filled with 2% perfluorobenzene in CDCl$_3$ or 5% of trifluoroacetic acid in D$_2$O was inserted into the NMR tube as the internal $^{19}$F chemical shift standard. Before each NMR measurement, the sample was bubbled with a stream of nitrogen or oxygen gas for 10 minutes on an ice bath. High resolution mass spectra (HRMS) were recorded on a Micromass GCT (GC-EI/CI Time of Flight Mass Spectrometer) with Electron Ionization (EI) resource. HPLC purification and analysis was performed on Aglient 1100 chromatograph systems using FlouroFlash® columns. Water and methanol were used as eluents; the flow rate for analytical and preparative runs was 1 and 5 mL/min respectively. The free fluorinated chelator is denoted as FC and fluorinated metal chelates are denoted as FC-M$^{x+}$, with $x+$ representing the valence of the metal ion, such as FC-Tb$^{3+}$. 
Synthesis of fluorinated chelates

Compound 1 is from Sigma-Aldrich; compound 5 is from Macrocyclics. They were used without further purification. The synthesis route is depicted in the following scheme. From tetryaethylene glycol 1, its two hydroxyl groups were sequentially transformed into an azido group and a perfluoro-tert-butoxyl group, respectively, to give fluorinated azide 3. After reduction of the azido group in 3, amine 4 was then coupled with DOTA-tri-tert-Butyl-ester 5 yielded 6. Finally, the fluorinated chelator FC was prepared on a 5-gram scale after removal of its three tert-butoyl groups in 6.

**Compound 2** To a stirred solution of tetryaethylene glycol 1 (45.6 mL, 264.0 mmol) in dichloromethane (DCM, 500 mL) was added 4-N,N-dimethylaminopyridine (5.0 g, 4.1 mmol) and triethylamine (44.5 mL, 317.0 mmol). After cooling to 0°C, methanesulfonyl chloride (16.5 mL, 211.2 mmol) was added dropwise to the solution and the resulting mixture was stirred for an additional hour at room temperature. The reaction mixture was washed with 2N HCl (100 mL, twice), brine (100 mL, twice), dried over anhydrous sodium sulfate and concentrated under vacuum to yield 2.

The resulting white solid was dissolved in THF (100 mL) and cooled to 0°C under nitrogen atmosphere. Phosphorus trichloride (48.0 mL, 0.30 mol) was added dropwise and the solution was allowed to stir at room temperature for 1 hour. After filtration, the filtrate was concentrated under vacuum to yield 3.

The reaction mixture was centrifuged and the aqueous layer was subjected to HPLC purification to give the pure chelate FC-Gd$^{3+}$.

General Information of NMR experiments:

All the NMR experiments were conducted on Varian INOVA 500 spectrometer equipped with a $^{1}\text{H}/^{19}\text{F}^{13}\text{C}/^{15}\text{N}$ 5mm Triple resonance PFG probe.

Calibrated 90° pulse was used as the transmitter pulse. The relaxation delay varied according to the different samples, but larger than $5 \times T_1$. Inversion-Recovery\(^1\) and CPMG (Carr-Purcell-Meiboom-Gill)\(^2\) sequences were used to measure the relaxation times $T_1$ and $T_2$, respectively. The parameters of $T_1$ and $T_2$ measurements are optimized according to the different relaxation time of these samples. All the $^{19}\text{F}$ chemical shifts were referenced to TFA (a capillary filled with 5% of trifluoroacetic acid in D$_2$O was inserted into the NMR tube) at δ -76.55 ppm.

Table S1. Effects of pH and temperature on the $^{19}$F chemical shift ($\delta$) and relaxation times ($T_1$ & $T_2$) of fluorinated chelates. All measurements were conducted in PBS saturated with N2.

Notes on experimental error estimate in relaxation time determination:
1. $T_1$ of FC-Y$^{3+}$ was measured 5 times at pH 6, 25°C to give the experimental error.
   $1431 \pm 5$ ms
2. $T_2$ of FC-Y$^{3+}$ was measured 10 times at pH 6, 25°C to give the experimental error.
   $1234 \pm 34$ ms
3. $T_1$ of FC-Gd$^{3+}$ was measured 12 times at pH 6, 25°C to give the experimental error.
   $3.917 \pm 0.030$ ms
4. $T_2$ of FC-Gd$^{3+}$ was measured 12 times at pH 6, 25°C to give the experimental error.
   $1.071 \pm 0.030$ ms
Table S2. Effects of BSA and human sera on the $^{19}$F chemical shift ($\delta$) and relaxation times ($T_1$ & $T_2$) of fluorinated chelates. For PBS and 10% BSA in PBS measurements, the solutions were saturated with N$_2$.
