Large-scale synthesis of uniform silver orthophosphate colloidal nanocrystals exhibiting high visible light photocatalytic activity

Cao-Thang Dinh, Thanh-Dinh Nguyen, Freddy Kleitz, and Trong-On Do*

Experimental Section

Chemicals: All chemicals were used as received; silver nitrate (AgNO₃), methylene blue (MB), oleylamine (OM), phosphoric acid (H₃PO₄), ammonium hydroxide (NH₄OH) were purchased form Aldrich. Absolute ethanol and toluene solvents were of analytical grade and were also purchased form Aldrich.

Synthesis of 8 nm Ag₃PO₄ nanocrystals: Typically, for the synthesis of about 10 g of 8 nm Ag₃PO₄ NCs, silver nitrate (0.1 mole) and OM (0.2 mole) were dissolved in 300 ml of toluene. To this mixture, H₃PO₄ (0.1 mole) dissolved in 100 ml of ethanol was then gradually added under stirring. The solution changed from colorless to yellow, indicating the formation of Ag₃PO₄ NCs. After 30 minutes of stirring, excess ethanol was added to precipitate Ag₃PO₄ NCs. The obtained NCs were then re-dispersed in 300 ml toluene and reprecipitated in ethanol. This process was repeated three times to remove all unreacted reagents.

Synthesis of Ag₃PO₄ nanocrystals with different sizes: The procedures for the synthesis of 10 nm, 12 nm, 14nm and 16 nm Ag₃PO₄ NCs were similar to that of 8 nm Ag₃PO₄ NCs, except that 2.5 g, 5.0 g, 7.5 g, and 10 g of water was added, respectively, to the H₃PO₄ solution in ethanol before it was added to the solution containing silver ions and OM.
Removing OM surfactant from Ag₃PO₄ NCs surface: The as-synthesized Ag₃PO₄ NCs were treated with dilute NH₄OH solution to remove OM surfactant. Typically, 10 mmol of as-synthesized Ag₃PO₄ NCs was dispersed in 100 ml toluene. To this solution, a mixture containing 1 mmol NH₄OH, 25 ml ethanol and 25 ml toluene was gradually added under stirring. After 1 h of additional stirring, the mixture was centrifuged to obtain a precipitate of Ag₃PO₄ NCs which was then redispersed in 100 ml of ethanol. To this mixture was gradually added a solution of 50 ml ethanol containing 1 mmol NH₄OH. After 1 h of stirring, the Ag₃PO₄ NCs obtained through centrifugation was dispersed in water and ready for photocatalytic tests.

Synthesis of micron-sized Ag₃PO₄ and N-doped TiO₂-P25: Ag₃PO₄ particles with micrometer size was synthesized as previously reported. Briefly, appropriate amounts of Na₃PO₄ and AgNO₃ were thoroughly mixed until the initial white color changed to yellow. The mixture was then washed with distilled dried at 70°C in air overnight. N-doped TiO₂-P25 was obtained by heat treating TiO₂-P25 at 550°C under a flow of NH₃ for 3h.

Characterization: Transmission electron microscopy (TEM) images of Ag₃PO₄ NCs were obtained on a JOEL JEM 1230 operated at 120kV. Samples were prepared by placing a drop of a dilute toluene dispersion of NCs onto a 200 mesh carbon coated copper grid and evaporated immediately at ambient temperature. The NC size analysis was carried out by manually digitizing the high magnification TEM images with Image Tool. XPS measurements were carried out in an ion-pumped chamber (evacuated to 10-9 Torr) of a photoelectron spectrometer (Kratos Axis-Ultra) equipped with a focused X-ray source (Al Ka, hv = 1486.6 eV). The binding energy of the samples was calibrated by setting the C 1s peak to 285 eV. Peak deconvolution were performed by means of a standard CasaXPS software (v.2.3.13; product of CasaXPS Software Ltd., USA) to resolve the separate constituents after background subtraction. Powder X-ray diffraction patterns of the samples were obtained on a Bruker SMART APEXII X-ray diffractometer equipped with a Cu Ka radiation rource.
(l=1.5418 Å). The UV-visible absorbance spectra were recorded on a Cary 300 Bio UV-visible spectrophotometer. Specific surface areas of the samples were measured by BET method (N2 adsorption) with a Quantachrome Autosorb-1 system.

Photocatalysis: Photocatalytic activities of the samples were evaluated by the photocatalytic decomposition of Methylene Blue (MB). A mixture of MB aqueous solution (15 ppm, 100 ml) and the given photocatalyst (30 mg) was magnetically stirred in absence of light for 60 minutes to ensure adsorption-desorption equilibrium between the photocatalyst and MB. The mixture was then stirred under visible light irradiation using a 40W compact fluorescent lamp. At given time intervals, 3 ml of the suspension was collected and centrifuged to remove photocatalyst particles. UV-vis adsorption spectrum of the centrifugated solution was recorded using a Cary 300 Bio UV-visible spectrophotometer to determine the conversion of the reaction.
