Experimental Details:

**General:** All chemicals were obtained from Sigma Aldrich or Spectrochem India and were used as received. Thin layer chromatography (TLC) was carried out on aluminium plates coated with silica gel mixed with fluorescent indicator having particle size of 25 µm and was sourced from Sigma Aldrich. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker 500 MHz spectrometer in DMSO-$d_6$ with TMS as standard. Infra Red spectra were recorded in KBr pellet using Varian 3100 FT-IR instrument. The circular dichroism (CD) spectra were performed in THF solvent using Applied Photophysics-Chirascan Circular Dichroism Spectrometer.

**Theoretical Calculations:** The geometry optimization was done using HF level 6-31G (d,p) basis set in gas phase in Gaussian 03 program.

**SEM Images:** The morphologies of the xerogels were investigated in a field emission scanning electron microscope (FE-SEM) apparatus (JEOL, JSM-6700F). The samples were platinum coated with thickness of 40 nm by sputtering technique in argon atmosphere and were observed at a voltage of 5 kV. The investigated gel samples were 1 (0.5 wt% gel in THF/MeOH 1:12), 2 (1 and 2 wt% gel in glacial Acetic Acid), and 3 (3 wt% gel in CHCl$_3$/CS$_2$ 1:3).

**Second Harmonic Generation (SHG) Measurements:** Q-switched Nd:YAG laser of fundamental wavelength 1064 nm (Spectra Physics, PROLAB 170, pulse width 10 ns and repetition rate 10 Hz) was used as the source of light for measuring the SHG efficiency of the compounds with respect to similar grain size KDP. The energy of the laser beam was kept at 2.60 mJ/pulse. The beam was focused onto a glass capillary, using a converging lens of 200 mm focal length. The incoherently scattered SH photons were collected in the transverse direction using a combination of a monochromator and a photomultiplier tube. The second harmonic signal was then sampled, averaged over 512 shots and was recorded in a digital storage oscilloscope.

**Dielectric Measurements:** The dielectric constant measurement was performed using an impedance analyzer HP 4192A.

**Measurement of Electric Hysteresis loop:** The measurement of ferroelectric properties was done using a Radiant Technologies ferroelectric tester (model Premier Precision II). The measurements were done at room temperature with powder sample in pellet form immersed in an insulating oil. The powder sample (1) was pressed uniaxially at 2 ton pressure to yield a uniform disk pellet of 3 mm diameter and 1.56 mm in thickness. The samples of compound 2, compound 3 and 3 (xerogel) were prepared by applying 5 kg/cm$^2$ pressure to yield pellets of 3 mm in diameter and 1.33, 0.82 and 1.25 mm in thickness, respectively. The obtained pellets were subsequently turned to a electrode using Ag paste.
Synthesis of 1:

**Synthetic Procedure for 1** - In a 100 mL round bottomed flask cholesterylchloroformate (4.10 g, 8.80 mmol) was taken in 60.0 mL of dry chloroform.
