for

Control of electron-transfer reduction by protonation of zinc octabutoxyphthalocyanine assisted by intramolecular hydrogen bonding

Tatsuhiko Honda, Takahiko Kojima,* and Shunichi Fukuzumi*
Experimental Section

Materials. Chemicals were purchased from commercial sources and used without further purification, unless otherwise noted. Benzonitrile (PhCN) used for spectroscopic and electrochemical measurements was distilled over phosphorus pentoxide prior to use.\(^1\) H\(_2\)(OBu)\(_8\)Pc, Zn(OBu)\(_8\)Pc, and Zn(SBu)\(_8\)Pc, were synthesized according to the reported procedures.\(^2\) [Ru(bpy)\(_3\)](PF\(_6\))\(_3\) was prepared from tris(2,2'-bipyridyl)ruthenium(II) chloride hexahydrate by the oxidation with PbO\(_2\).\(^3\)

Synthesis of [Zn(OBu)\(_8\)PcH](CH\(_3\)COO). The mixture of Zn(OBu)\(_8\)Pc in CHCl\(_3\) and excess amount of acetic acid was evaporated. The resulting solid was washed with hexane and dried in vacuo to give [Zn(OBu)\(_8\)PcH](CH\(_3\)COO) as red-brown powder quantitatively. Elemental analysis (%) calcd for C\(_{66}\)H\(_84\)N\(_8\)O\(_{10}\)Zn•(H\(_2\)O)\(_0\).5: C 64.77, H 7.00, N 9.16; found: C 64.66, H 6.79, N 9.13.

Spectroscopic Measurements. UV-vis spectroscopy was carried out on a Shimadzu UV-3100PC spectrometer or a Hewlett Packard 8453 diode array spectrometer at room temperature using 1 cm cells. Equilibrium constants (log \(K\)) of the protonated phthalocyanines [Equation (1)] were determined by the Hill equation [Equation (2)], which analyzes changes of absorption spectra during the titration as a function of the concentration of added acids.\(^4\)

\[
Pc + n HA \rightleftharpoons K \text{PcH}^\text{n+} + n A^- \quad (1)
\]

\[
\log \left[\frac{(A_o - A_i)}{(A_f - A_o)}\right] = n \log [HA] + \log K \quad (2)
\]

where \(A_o\) is observed absorbance, \(A_i\) is an absorbance of Pc, \(A_f\) is an absorbance of PcH\(_n\)^\text{n+}, \(n\) is a number of proton to react, and [HA] denotes the concentration of acid, respectively.

\(^1\)H NMR spectra were recorded on a JEOL A-300 spectrometer and chemical shifts were determined relative to the residual solvent peaks. The fluorescence spectra were measured by using an absolute PL quantum yield measurement system (Hamamatsu photonics Co., Ltd., C9920-02) by excitation at 430 nm. Phosphorescence spectrum was measured by using a SPEX Fluorolog \(\tau\)3 spectrophotometer.

The energy levels of singlet excited states of Zn(II)-phthalocyanines were determined on the basis of the averaged values (in eV) of their absorption and fluorescence maxima.
The energy levels of their tripled excited states were calculated by using the emission maxima of their phosphorescence spectra.

**Time-Resolved Transient Absorption Measurements.** Nanosecond time-resolved transient absorption measurements were performed using a laser system provided by UNISOKU Co., Ltd. Measurements of nanosecond transient absorption spectra were performed according to the following procedure. A deaerated solution was excited by a Panther optical parametric oscillator pumped by a Nd:YAG laser (Continuum, SLII-10, 4-6 ns fwhm) at $\lambda = 430$ nm. The photodynamics was monitored by continuous exposure to a xenon lamp (150 W) as a probe light and a photomultiplier tube (Hamamatsu 2949) as a detector. The equilibrium constant of monoprotonation at the triplet excited state ($K^*$) was determined from the observed rate constant of triplet decay by using Equation (3),

$$\frac{(k_{\text{obs}} - k_1)}{(k_2 - k_{\text{obs}})} = K^*[\text{HA}]$$

where $k_{\text{obs}}$ is the observed rate constant of the decay of the triplet excited state, $k_1$ is rate constant of that of Zn(OBu)$_8$Pc, $k_2$ is rate constant of that of Zn(OBu)$_8$PcH$^+$, and [HA] denotes the concentration of acid.

**Electrochemical Measurements.** Cyclic voltammetry (CV) was performed on an ALS 630B electrochemical analyzer and was conducted in deaerated PhCN containing 0.1 M [(n-Bu)$_4$N]PF$_6$ (TBAPF$_6$) as a supporting electrolyte at room temperature. A conventional three-electrode cell was used with a platinum working electrode (surface area of 0.3 mm$^2$) and a platinum wire as the counter electrode. The Pt working electrode (BAS) was routinely polished with BAS polishing alumina suspension and rinsed with acetone before use. The potentials were measured with respect to the Ag/AgNO$_3$ (0.01 M) reference electrode. All potentials (vs. Ag/Ag$^+$) were converted to values vs. SCE by adding 0.29 V.$^6$ All electrochemical measurements were carried out under an atmospheric pressure of nitrogen.
