1. General Information

All manipulations were carried out in an Argon atmosphere by standard Schlenk techniques or in a glovebox. Glassware was dried prior to use by heating it in vacuo. THF was dried with sodium via distillation, all other solvents were dried with a Grubbs apparatus and degassed via repeated freeze-pump-thaw cycles. All other commercially available compounds were used without further purification. Compounds p-toluoyl chloride phenylhydrazone, methylisocyanide und 1-methyl-2-phenyl-4-p-tolyl-1,2,3-triazolium-chloride 1 were prepared by following procedures described in literature.\(^1\)\(^1\)H- and \(^13\)C-NMR-spectra were recorded on a 400 MHz Bruker Avance III or a 400 MHz Bruker Avance DPX spectrometer at a Temperature of 298 K, if not indicated otherwise. The spectra were referenced in parts per million (ppm) with an internal standard using the residual solvent shifts. Abbreviations for signal multiplicities are: singulett (s), dublett (d), triplett (t), quartet (q), multiplet (m), broad (br). Column chromatography was performed over silica gel (40-63 µm). IR spectra were recorded on a Varian 670 FT-IR Spectrometer. ESI-HRMS analysis was performed on a Thermo Scientific LTQ Orbitrap XL by Thermo Fisher Scientific. Crystallographic data collection were carried out on an area detecting system (APEX II, κ-CCD) at the window of a rotating anode (Bruker AXS, FR591) and graphite-monochromated Mo-K\(_\alpha\) radiation (\(λ = 0.71073 \) Å). Elemental Analyses were conducted by the micro-analytical laboratory of the TUM.

2. Synthetic Procedures

2.1. Preparation of 1-methyl-2-phenyl-4-p-tolyl-1H-1,2,3-triazol-5-amine (2).

Following a procedure reported by Herrmann and coworkers\(^2\) this reaction was performed in an apparatus specifically designed for this reaction type: A graduated three-necked Schlenk flask, equipped with a pressure valve, an addition tube, and a magnetic stirrer and connected via a glass tube to another Schlenk flask equipped with an ammonia inlet and a pressure valve, was positioned in a cooling bath with dry ice. The three-necked flask was charged with sodium (5.0 g) before ammonia was condensed at -78 °C. By removing the dry ice bath from the three-necked flask and placing it underneath the second Schlenk flask ammonia was allowed to condense into the second one. 100 mL of dry ammonia were then added to a suspension of 1-methyl-2-phenyl-4-p-tolyl-1,2,3-triazolium-chloride 1 (2.00 g, 7.00 mmol) in 20 mL THF. The solution was stirred at reflux of liquid ammonia at -33 °C until 1 was completely dissolved. Via the addition tube NaH (0.185 g, 7.7 mmol) was added under vigorous gas evolution. After stirring under reflux for two hours, liquid ammonia was evaporated and the remaining THF solution was filtered through a cannula. At RT, THF was quickly removed, the remaining oil redissolved in C\(_6\)H\(_6\) and lyophilized to yield 2 (1.69 g, 91 %) as a yellow solid, that was stored at -30 °C under Argon.

2.2. Synthetic procedure for the preparation of 3 and 4 using silver oxide:

2.2.1. Preparation of (1-Methyl-2-phenyl-4-tolyl-1,2,3-triazol-5-ylidenediyl)(Cyclooctadienyl) Rh(I)Cl (RhCOD) and (1-Methyl-2-phenyl-4-tolyl-1,2,3-triazol-5-ylidenediyl)(Cyclooctadienyl)Ir(I)Cl (IrCOD)

Scheme S2. Synthesis of RhCOD and IrCOD using 1.

Silver oxide (68.0 mg, 0.29 mmol), the metal precursor [M(COD)Cl]₂ (0.14 mmol) (M = Rh or Ir) and 1 (85.0 mg, 0.29 mmol) were suspended in 5 mL of THF at -78 °C. The suspension was stirred for 12 h and allowed to slowly warm up to room temperature during that time. The solvent was removed under vacuo and the residue was washed with Et₂O (3 x 3 mL). The raw product was purified by column chromatography (SiO₂, CH₂Cl₂). After removing the solvent RhCOD (130 mg, 91 %) or IrCOD (144 mg, 85 %) were obtained as bright yellow solids.

For characterization of these compounds see 2.3.
2.3. Synthetic procedure for the preparation of 3 and 4 using 2:

2.3.1. Preparation of (1-Methyl-2-phenyl-4-tolyl-1,2,3-triazol-5-ylidenyl)(Cyclooctadienyl) Rh(I)Cl (RhCOD) and (1-Methyl-2-phenyl-4-tolyl-1,2,3-triazol-5-ylidenyl)(Cyclooctadienyl)Ir(I)Cl (IrCOD)

Scheme S3. Synthesis of RhCOD and IrCOD using 2.

In a glovebox [M(COD)Cl]2 (0.10 mmol) and 2 (53.2 mg, 0.20 mmol) were transferred into a Schlenk tube. At -78 °C 7 mL DCM were added to the solids. The suspension was stirred for 12 h and allowed to slowly warm up to room temperature during that time. The solvent was removed under vacuo and the residue was washed with Et2O (3 x 2 mL), extracted with 3 mL of DCM and filtered. Removal of the solvent in vacuo afforded RhCOD (51 mg, 52 %) or IrCOD (74.8 mg, 64 %).

2.4. Preparation of (1-Methyl-2-phenyl-4-tolyl-1,2,3-triazol-5-ylidenyl)(Dicarbonyl)Ir(I)Cl (4).

At room temperature CO was bubbled through a solution of \textit{IrCOD} (0.237 g, 0.405 mmol) in 15 mL of dichloromethane for 20 min while stirring. During that time the color of the solution changed from bright to pale yellow. The solvent was removed by evaporation under vacuo and the remaining crude product was purified via column chromatography (SiO\textsubscript{2}, CH\textsubscript{2}Cl\textsubscript{2}), yielding 4 (203 mg, 94 %) as a pale yellow solid.

3. Crystallographic data

General: Crystallographic details are summarized in Table 1. X-ray diffraction measurements were performed on single crystals coated with Paratone oil and mounted on Kaptan loops. Each crystal was frozen under a stream of dinitrogen while data were collected on an X-ray diffractometer equipped with a CCD detector (APEX II, κ−CCD), a rotating anode (Bruker AXS, FR591) with MoKα radiation (λ = 0.71073 Å), and a graphite monochromator by using the SMART software package. A matrix scan using at least 20 centered reflections was used to determine the initial lattice parameters. Reflections were merged and corrected for Lorenz and polarization effects, scan speed, and background using SAINT 4.15. Absorption corrections, including odd and even ordered spherical harmonics were performed using SADABS. Space group assignments were based upon systematic absences, E statistics, and successful refinement of the structures. Structures were solved by direct methods with the aid of successive difference Fourier maps, and were refined against all data using WinGX based on SHELXS-97 oder Sir-92. Hydrogen atoms were either located (in case of 2) and refined with isotropic replacement parameters or assigned to ideal positions (in case of 3, 4 and 5a) and refined using a riding model with an isotropic thermal parameter 1.2 times that of the attached carbon atom (1.5 times for methyl hydrogens). All non-hydrogen atoms were refined with anisotropic displacement parameters. Full-matrix least-squares refinements were carried out by minimizing Σw(Fo^2 - Fc^2)^2 with SHELXL-97 weighting scheme. The final residual electron density maps showed no remarkable features. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from International Tables for Crystallography. All structures were checked for possible problems by using Platon. Images of the crystal structures were generated by Diamond 3.1 and ORTEP. Crystallographic data (excluding structure factors) for 2, 3, 4, and 5a have been deposited with the Cambridge Structural database at www.ccdc.cam.ac.uk/products/csd and are available free of charge: CCDC-788089 (2), CCDC-797025 (4), CCDC-797026 (3), CCDC-849440 (5a). Special: for 2: The absolute configuration could not be determined since atoms that cause strong anomalous scattering were absent. Therefore the Friedel pairs were merged for the final refinement; for 4: Due to the small size of the crystal many weak reflections appear giving rise to poor R-values. To exclude these weak reflections, the data set was cut off at a resolution of 0.93 Å, resulting in less data, but slightly better R-values.

6. Computational Details

All calculations were performed with GAUSSIAN-03 \cite{14} using the density functional / Hartree-Fock hybrid model Becke3LYP \cite{15} and the split valence double-\(\zeta\) (DZ) basis set 6-31G* \cite{16}. No symmetry or internal coordinate constraints were applied during optimizations. All reported intermediates were verified as being true minima by the absence of negative eigenvalues in the vibrational frequency analysis, while transition states were located according to the Berny algorithm. Transition-state structures (indicated by TS) were located using the Berny algorithm \cite{17} until the Hessian matrix had only one imaginary eigenvalue. The identities of all transition states were confirmed by IRC calculations, and by animating the negative eigenvector coordinate with MOLDEN \cite{18} and GaussView \cite{19}. Approximate free energies (\(\Delta G\)) and enthalpies (\(\Delta H\)) were obtained through thermochemical analysis of frequency calculations, using the thermal correction to Gibbs free energy as reported by GAUSSIAN-03. This takes into account zero-point effects, thermal enthalpy corrections, and entropy. All energies reported in this paper, unless otherwise noted, are free energies at 298 K, using unscaled frequencies. All optimizations are PCM calculations \cite{20} to include solvation effects with THF (\(\varepsilon = 7.4257\)) as solvent.
