**General Information**

All reactions were monitored by TLC on Kieselgel 60 F\(_{254}\) (E. Merck). Detection was achieved by charring with vanillin-H\(_2\)SO\(_4\) reagent. Preparative column chromatography was performed using 230-240 mesh Merck silica gel (purchased from Aldrich). Optical rotations were measured with a JASCO DIP-370 digital polarimeter, using a sodium lamp (\(\lambda = 589\) nm) at 20°C. Micro-waves irradiation was performed in a CEM Discover\textsuperscript{®} System. All NMR experiments were recorded at 300.13 and 600.13 MHz using Bruker DPX300 and IPSO600 spectrometers respectively equipped with a Z-gradient unit for pulsed-field gradient spectroscopy. Assignments were performed by stepwise identification using COSY, HSQC and HMBC experiments using standard pulse programs from the Bruker library. Chemical shifts are given relative to external TMS with calibration involving the residual solvent signals. When D\(_2\)O was used, TMS was used as internal standard reference in a previous \(^{13}\)C NMR experiment performed in the same experimental conditions. The length of the 90° pulse was approximately 7\(\mu\)s (\(^1\)H NMR) and 10\(\mu\)s (\(^{13}\)C NMR). 1D NMR data spectra were collected using 16 K data points. 2D experiments were run using 1K data points and 512 time increments. The phase-sensitive (TTPI) sequence was used and processing resulted in a 1K*1K (real-real) matrix. A 45° flip angle (3.5 \(\mu\)s) and a total recovery time of 5 s were used to ensure complete relaxation of the protons and quantitative measurements. The digital integration of the transformed spectra was performed after polynomial baseline correction. High-resolution mass spectra were recorded in positive mode on a ZabSpec TOF (Micromass, UK) tandem hybrid mass spectrometer with EBETOFS geometry. The compounds were individually dissolved in 1:1 water-MeCN at a concentration of 10 \(\mu\)g cm\(^{-3}\) and then infused into the electrospray ion source at a flow rate of 10 mm\(^3\) min\(^{-1}\) at 60°C. The mass spectrometer was operated at 4 kV whilst scanning the magnet at a typical range of 4000-100 Da. The mass spectra were collected as continuum profile data. Accurate mass measurement was achieved using polyethylene glycol as internal reference with a resolving power set to a minimum of 10\,000 (10% valley). Preparative HPLC was carried out with a Waters Prep LC 4000 System chromatograph fitted with evaporative light scattering detector PL-ELS 1000 (Polymer Laboratories) and a Prevail Carbohydrates
ES column (5 μm, 10 x 250 mm). Commercial reagents were used without purification. Air and/or moisture-sensitive reactions were carried out under an atmosphere of argon using oven/flamed-dried glassware and standard syringe/septa techniques.

The high-mannose oligosaccharides Man₅₄ used in the comparative ELLA experiments were purchased from Ludger (Abingdon, UK; Refs: CN-MAN5, CN-MAN6, CN-MAN7, CN-MAN8 and CN-MAN9) and stored at -20 °C. Purity was controlled by ¹H NMR.

3: Enzyme-Linked Lectin Assay (ELLA)

Nunc-Inmuno™ plates (MaxiSorp™) were coated overnight with yeast (Saccaromices cerevisae) mannan at 100 µL/well diluted from a stock solution of 10 µg·mL⁻¹ in 0.01 m phosphate buffer saline (PBS, pH 7.3 containing 0.1 mm Ca²⁺ and 0.1 mm Mn³⁺) at room temperature. The wells were then washed three times with 300 µL of washing buffer (containing 0.05% (v/v) Tween 20) (PBST). The washing procedure was repeated after each of the incubations throughout the assay. The wells were then blocked with 150 µL/well of 1% BSA/PBS for 1 h at 37 °C. After washing, the wells were filled with 100 µL of serial dilutions of horseradish peroxidase labelled concanavalin A lectin (ConA-HRP) from 10⁻¹ to 10⁻⁵ mg mL⁻¹ in PBS,
and incubated at 37 °C for 1 h. The plates were washed and 50 μL/well of 2,2'-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS) (0.25 mg·mL⁻¹) in citrate buffer (0.2 M, pH 4.0 with 0.015% H₂O₂) was added. The reaction was stopped after 20 min by adding 50 μL/well of 1 M H₂SO₄ and the absorbances were measured at 405 nm. Blank wells contained citrate-phosphate buffer. The concentration of lectin-enzyme conjugate that displayed an absorbance between 0.8 and 1.0 was used for inhibition experiments.

In order to carry out the inhibition experiments, each oligosaccharide (Man₅₋₉ or 1) was added in a serial of 2-fold dilutions (60 μL/well) in PBS with 60 μL of the desired Con A-HRP conjugate concentration on Nunclon™ (Delta) microtiter plates and incubated for 1 h at 37 °C. The above solutions (100 μL) were then transferred to the lactose polymer-coated microplates, which were incubated for 1 h at 37 °C. The plates were washed and the ABTS substrate was added (50 μL/well). Color development was stopped after 20 min and the absorbances were measured. The percent of inhibition was calculated as follows:

\[
\% \text{ Inhibition} = \frac{A_{(\text{no inhibitor})} - A_{(\text{with inhibitor})}}{A_{(\text{no inhibitor})}} \times 100.
\]

Results in triplicate were used for the plotting the inhibition curves for each individual ELLA experiment. Typically, the IC₅₀ values (concentration required for 50% inhibition of the Con A-yeast mannan association) obtained from several independently performed tests were in the range of ±12%. Nevertheless, the relative inhibition values calculated from independent series of data were highly reproducible.
