**General methods:** Unless stated otherwise, reactions were performed under nitrogen atmosphere using oven dried glassware. Reactions were monitored by thin layer chromatography (TLC) on silica gel plates (60 F254), visualizing with ultraviolet light or iodine spray. Flash chromatography was performed on silica gel (230–400 mesh) using distilled hexane, ethyl acetate. $^1$H NMR and $^{13}$C NMR spectra were recorded in CDCl$_3$ or DMSO-$d_6$ solution by using 400 or 100 MHz spectrometers, respectively. Proton chemical shifts ($\delta$) are relative to tetramethylsilane (TMS, $\delta = 0.00$) as internal standard and expressed in ppm. Spin multiplicities are given as s (singlet), d (doublet), dd (doublet of doublet), td (triplet of doublet), t (triplet) and m (multiplet) as well as b (broad). Coupling constants ($J$) are given in hertz. Infrared spectra were recorded on a FT-IR spectrometer. MS spectra were obtained on an Agilent 6430 series Triple Quard LC-MS / MS spectrometer. High-resolution mass spectra (HRMS) were recorded using a Waters LCT Premier XE instrument. Melting points (mp) were by using Buchi B-540 melting point apparatus and are uncorrected. Chromatographic purity by HPLC (Agilent 1200 series Chem Station software) was determined by using area normalization method and the condition specified in each case: column, mobile phase (range used), flow rate, detection wavelength, and retention times.

**Single crystal X-ray data for compound 5k.**

Single crystals suitable for X-ray diffraction of 5k was grown from methanol. The crystals were carefully chosen using a stereo zoom microscope supported by a rotatable polarizing stage. The data were collected at room temperature on Bruker’s KAPPA APEX II CCD Duo with graphite monochromated Mo-Kα radiation (0.71073 Å). The crystals were glued to a thin glass fibre using FOMBLIN immersion oil and mounted on the diffractometer. The intensity data were processed using Bruker’s suite of data processing programs (SAINT), and absorption corrections were applied using SADABS. The crystal structures were solved by direct methods using SHELXS-97 and refined by full matrix least-squares refinement on $F^2$ with anisotropic displacement parameters for non-H atoms, using SHELXL-97.

**PDE4B protein production and purification**

PDE4B1 cDNA was sub-cloned into pFAST Bac HTB vector (Invitrogen) and transformed into DH10Bac (Invitrogen) competent cells. Recombinant bacmids were tested for integration by PCR analysis. Sf9 cells were transfected with bacmid using Lipofectamine 2000 (Invitrogen) according to manufacturer’s instructions. Subsequently, P3 viral titer was amplified, cells were infected and 48 h post infection cells were lysed in lysis buffer (50 mM Tris-HCl pH 8.5, 10 mM 2-mercaptoethanol, 1 % protease inhibitor cocktail (Roche), 1 %
Recombinant His-tagged PDE4B protein was purified as previously described elsewhere. Briefly, lysate was centrifuged at 10,000 rpm for 10 min at 4 °C and supernatant was collected. Supernatant was mixed with Ni-NTA resin (GE Life Sciences) in a ratio of 4:1 (v/v) and equilibrated with binding buffer (20 mM Tris-HCl pH 8.0, 500 mM-KCl, 5 mM imidazole, 10 mM 2-mercaptoethanol and 10% glycerol) in a ratio of 2:1 (v/v) and mixed gently on rotary shaker for 1 hour at 4 °C. After incubation, lysate-Ni-NTA mixture was centrifuged at 4,500 rpm for 5 min at 4 °C and the supernatant was collected as the flow-through fraction. Resin was washed twice with wash buffer (20 mM Tris-HCl pH 8.5, 1 M KCl, 10 mM 2-mercaptoethanol and 10% glycerol). Protein was eluted sequentially twice using elution buffers (Buffer I: 20 mM Tris-HCl pH 8.5, 100 mM KCl, 250 mM imidazole, 10 mM 2-mercaptoethanol, 10% glycerol, Buffer II: 20 mM Tris-HCl pH 8.5, 100 mM KCl, 500 mM imidazole, 10 mM 2-mercaptoethanol, 10% glycerol). Eluates were collected in four fractions and analyzed by SDS-PAGE. Eluates containing PDE4B protein were pooled and stored at -80 °C in 50% glycerol until further use.

**PDE4 enzymatic assay**

The inhibition of PDE4 enzyme was measured using PDElight HTS cAMP phosphodiesterase assay kit (Lonza) according to manufacturer’s recommendations. Briefly, 10 ng of in house purified PDE4B1 or 0.5 ng commercially procured PDE4D2 enzyme was pre-incubated either with DMSO (vehicle control) or compound for 15 min before incubation with the substrate cAMP (5 µM) for 1 hour. The reaction was halted with stop solution and reaction mix was incubated with detection reagent for 10 minutes in dark. Dose response studies were performed at 13 different concentrations ranging from 200 µM to 0.001 µM. Luminescence values (RLUs) were measured by a Multilabel Plate Reader (PerklinElmer 1420 Multilabel Counter). The percentage of inhibition was calculated using the following formula and the IC$_{50}$ values were determined by a nonlinear regression analysis from dose response curve using Graphpad Prism software (San Diego, U.S.A). IC$_{50}$ values are presented as mean ± SD.

$$\% \text{ inhibition} = \left( \frac{\text{RLU of vehicle control} - \text{RLU of inhibitor}}{\text{RLU of vehicle control}} \right) \times 100$$
Some of the synthesized compounds were tested for their PDE4B inhibitory potential \textit{in vitro} at 30 $\mu$M using PDE4B enzyme\textsuperscript{7} and rolipram as a reference compound.

\textbf{Molecular Modeling Studies}

\textbf{Docking Method:} The docking studies of molecules were performed using the Maestro, version 9.2\textsuperscript{1}. The compounds were sketched in 3D format using build panel and LigPrep module was used to produce low-energy conformers and to refine the structural parameters of molecules. The crystal structure of PDE4B (PDB ID: 3D3P)\textsuperscript{2} was obtained from the protein data bank. The protein was prepared by giving preliminary treatment like adding hydrogen, adding missing residues, refining the loop with prime and finally minimized by using OPLS-2005 force field. Grids for molecular docking were generated with bound co-crystallized ligand. Compounds were docked using Glide in extra-precision mode,\textsuperscript{3} with up to three poses saved per molecule. Ligands were kept flexible by producing the ring conformations and by penalizing non-polar amide bond conformations, whereas the receptor was kept rigid throughout the docking studies. All other parameters of the Glide module were maintained at their default values. The lowest energy
conformation was selected and the ligand interactions (hydrogen bonding and hydrophobic interaction) with the active sites of PDE4B were determined.

**Docking Discussion:** The molecular docking was performed using most potent molecules against PDE4B (Table 1). Docking studies predicted good binding interaction with the PDE4B enzyme. In case of molecule 5e oxygen atom of morpholine ring and CO group participated in H-bonding with NH of His-278 and OH of Tyr 233 respectively. A pi-pi stacking between the molecule 5e and Phe-446 was also observed (Figure 1). The morpholine ring of molecule 5e was found to be well occupied in the partially charged pocket of active site (Figure 2). In case of molecule 3n, the hydrophobic interactions were found to be the primary binding interactions. Aromatic rings of molecule 3n participated in good pi-pi stacking with active site residues (Tyr-233, Phe-414, and Phe-446) of the protein. In addition a hydrogen bond interaction between molecule 3n and amino group of Gln-443 was also observed (Figure 3 and 4).
