1. Materials and instruments

The synthetic routes for dyes XS54–57 are shown in Scheme S1-4. 3,3’-dibromo-2,2’-bithiophene, n-butyllithium, Pd(PPh$_3$)$_4$, Pd$_2$(db)$_3$, SnBu$_3$Cl, t-ButONa, BINAP and cyanocertic acid were purchased from Energy Chemical (China). 4-tertpyridine (TBP) and 0.1 M Lithium bis–(trifluoromethanesulfonyl)imide (LiTFSI) were purchased from Aldrich. N,N-Dimethylformamide was dried over and distilled from CaH$_2$ under an atmosphere of nitrogen. Phosphorus oxychloride was freshly distilled before use. Dichloromethane was distilled from calcium hydride under nitrogen atmosphere. All other solvents and chemicals used in this work were analytical grade and used without further purification.

$^1$H NMR and $^{13}$C NMR spectra were recorded on a Bruker AM–300 or AM–400 spectrometer. The reported chemical shifts were against TMS. High resolution mass spectra were obtained with a Micromass GCT–TOF mass spectrometer.

2. Photophysical and electrochemical measurements

The absorption spectra of the dyes either in solution or on the adsorbed TiO$_2$ films were measured by HITACHI U-3310 spectrophotometer. Fluorescence measurements were carried out with a HITACHI F-4500 fluorescence spectrophotometer.

Cyclic voltammetry (CV) measurements for XS54-57 sensitized films were performed on a Zennium electrochemical workstation (ZAHNER), with sensitized electrodes as the working electrode, Pt–wires as the counter electrode, and an Ag/AgCl electrode as the reference electrode at a scan rate of 50 mV s$^{-1}$. Tetrabutylammonium perchlorate (TBAP, 0.1 M) and MeCN were used as supporting electrolyte and solvent, respectively. The measurements were calibrated using ferrocene as standard.
3. Fabrication of DSCs

The TiO$_2$ paste (particle size, 20 nm) consisting of 18 wt.% TiO$_2$, 9 wt.% ethyl cellulose and 73 wt.% terpineol was firstly prepared,$^{51}$ which was printed on a conducting glass (Nippon Sheet Glass, Hyogo, Japan, fluorine–doped SnO$_2$ over layer, sheet resistance of 10 Ω/sq) using a screen printing technique. Different thickness of the TiO$_2$ films (5 and 14 μm) were obtained by selection of screen mesh size and repetition of printing and the active area of cells is 0.156 cm$^2$. The film was dried in air at 120 °C for 30 min and calcined at 500 °C for 30 min under flowing oxygen before cooling to room temperature. The heated electrodes were impregnated with a 0.05 M titanium tetrachloride solution in a water–saturated desiccator at 70 °C for 30 min and sintered again to give a mesoscopic TiO$_2$ film. The TiO$_2$ electrode was stained by immersing it into a dye solution containing 300 μM sensitizers (DCM–Ethanol 1:4) for 24 h at room temperature. Then the sensitized–electrode was rinsed with dry ethanol and dried by a dry air flow. Note that, devices fabricated using 150 μM dyes solution yield comparable performance to those of the 300 μM dyes solution.

Pt catalyst was deposited on the FTO glass by coating with a drop of H$_2$PtCl$_6$ solution (40 mM in ethanol) with the heat treatment at 395 °C for 15 min to give photoanode. The dye–covered TiO$_2$ electrode and Pt–counter electrode were assembled into a sandwich type cell by a 25 μm–thick Surlyn (DuPont) hot–melt gasket and sealed up by heating. The cobalt electrolyte is composed of 0.25 M [Co(II)(phen)$_3$](PF$_6$)$_2$, 0.05 M [Co(III) (phen)$_3$](PF$_6$)$_3$, 0.5 M 4–tertpyridine (TBP) and 0.1M LiTFSI in acetonitrile, whereas the iodine electrolyte is composed of 0.6 M 1,2–dimethyl–3–n–propylimidazolium iodide (DMPImI), 0.1 M LiTFSI, 0.03 M I$_2$, and 0.5 M tertbutylpyridine in acetonitrile.
4. Characterization of DSCs

The photocurrent–voltage (J–V) characteristics of the solar cells were carried out using a Keithley 2400 digital source meter controlled by a computer and a standard AM1.5 solar simulator–Oriel 91160–1000 (300W) SOLAR SIMULATOR 2 x 2 BEAM. The light intensity was calibrated by an Oriel reference solar cell. A metal mask with an aperture area of 0.2 cm$^2$ was covered on a testing cell during all measurements. The action spectra of monochromatic incident photon–to–current conversion efficiency (IPCE) for solar cell were performed by using a commercial setup (QTest Station 2000 IPCE Measurement System, CROWNTECH, USA). We estimated the short circuit current density of cells based on the four dyes by integrating the IPCE values versus the sun AM1.5G spectrum, which are slightly lower than the measured short circuit photocurrent density and that calculated from the overlap integral of the IPCE curve with the standard AM1.5G solar emission spectra, implying that there existed a spectral mismatch between our solar simulating system and the standard AM1.5G irradiation. Similar phenomena have been reported by other groups.$^{52}$ In addition, the integration is performed only from 400 to 800 nm. The contribution from wavelength shorter than 400 nm is ignored, so that the calculated current may be underestimated. However, in view of the same conditions in the test, our approach is reliable for fair evaluation of the photovoltaic performance of the four dyes discussed in this work.

Charge densities at open circuit and intensity modulated photovoltage spectroscopy (IMVS) were performed on a Zennium electrochemical workstation (ZAHNER, Germany), which includes a green light emitting diode (LED, 532 nm) and the corresponding control system. The intensity-modulated spectra were measured at room temperature with light intensity ranging from 5 to 75 W m$^{-2}$, in modulation frequency ranging from 0.1 Hz to 10 kHz, and with modulation amplitude less than 5% of the light intensity.

Charge densities at open-circuit, measured by charge extraction technique,$^{33}$ were used to compare the conduction band positions in different DSCs. The IMVS is used to measure the time constants for charge recombination at open circuit ($\tau_{oc}$), which can be obtained by fitting either the real or imaginary part of the IMVS response (eq 1 and 2).$^{4,5}$

\begin{equation}
re(\Delta V_{oc}) = \frac{X_1}{1 + (\omega \tau_{oc}^{re})^2} \quad (1)
\end{equation}

\begin{equation}
im(\Delta V_{oc}) = -\frac{X_2 \omega \tau_{oc}^{im}}{1 + (\omega \tau_{oc}^{im})^2} \quad (2)
\end{equation}

Where $\text{im}(\Delta V_{oc})$ is the imaginary modulation of the photopotential ($\Delta V_{oc}$), $\text{re}(\Delta V_{oc})$ is the real modulation of the photopotential ($\Delta V_{oc}$), $X_1$, $X_2$, $\tau_{oc}^{re}$ and $\tau_{oc}^{im}$ are the fit parameters, $\omega$ is the circular frequency of the light modulation.

5. Computational Methods

The geometrical structures of the four dyes were optimized by performed density functional theory (DFT) calculations and time-dependent DFT (TDDFT) calculations of the excited states at the B3LYP/6-31+G(d) level with the Gaussian 03W program package.6

6. Experimental procedures

Compounds 5, 9a and 9b were prepared according to a slightly modified literature procedure starting from 3,3'-dibromo-2,2'-bithiophene.7 Dihexylcyclopentadithiophene was synthesized according to the literature.8

**Synthesis of compound 11a and 11b**
