**Methods**

**Electrode fabrication with active material.** A Co-Ni multiphase composite thin film was prepared by a new process (Fig S1). The cobalt precursor, cobalt nitrate hydrate (Co(NO$_3$)$_2$·6H$_2$O) and the nickel precursor (Ni(NO$_3$)$_2$·6H$_2$O) were added. The molar ratios of the Co(NO$_3$)$_2$·6H$_2$O : Ni(NO$_3$)$_2$·6H$_2$O was 4 : 6. The composite preparation process was started after the addition of 100ml of 1M LiOH solution as the precipitant and 10ml of 2 M hydroxylamine NH$_2$OH solution as the chelating agent by applying 0.9 V between the electrodes overnight at room temperature (25°C). The titanium (Ti) substrate used was pre-coated with a commercial activated carbon to form the anode and pre-coated with acetylene black to form the cathode, respectively. The obtained electrode surfaces were rinsed with deionized water and finally dried overnight at 60°C in air. The final loading amount was 15mg.

**FTIR studies.** Fig S2 shows the FTIR spectrum of the Co-Ni multiphase composite thin films. From the spectrum, it can be seen that the broad band centred around 3400 cm$^{-1}$ and 1500 cm$^{-1}$ is assigned to the stretching vibration mode of -OH group and the strong band around 520 cm$^{-1}$ is associated with the Co-O vibrations. The strong band observed around 660 cm$^{-1}$ corresponds to the Ni-O-H vibrations and the one around at 1380 cm$^{-1}$ corresponds to the NiO$_3$ vibrations. In summary, the spectrum indicates the presence of Co-O, Ni-O-H and -OH groups. It also confirms that the composite material is in the α- phase. Thus the formation of the α- phase Co-Ni multiphase composite thin films is supported by the FTIR studies. The results also support the presence of Co(OH)$_2$, CoOOH, and Ni(OH)$_2$ found by the XPS analysis as discussed in our manuscript.

**Cyclic voltammetry study.** The capacitance performance was primarily determined due to these Faradic reactions:

\[
\begin{align*}
\text{Co(OH)}_2 + \text{OH}^- & \leftrightarrow \text{CoOOH} + \text{H}_2\text{O} + e^- \quad (1) \\
\text{CoOOH} + \text{OH}^- & \leftrightarrow \text{CoO}_2 + \text{H}_2\text{O} + e^- \quad (2) \\
\text{Ni(OH)}_2 + \text{OH}^- & \leftrightarrow \text{NiOOH} + \text{H}_2\text{O} + e^- \quad (3)
\end{align*}
\]

The specific capacitance $C_{sp}$ of the electrode can be calculated according to the following relation:

\[
C = \frac{I \cdot \Delta t}{m \Delta V}
\]

where $I$ is the discharge current [A], $\Delta t$ is the discharge time [s] and $\Delta V$ is the potential window [V] of the discharge process, and $m$ is the mass of the active materials [g].

**Galvanostatic charge-discharge analysis.** Fig S3 shows the galvanostatic charge-discharge curves at various current densities. The shape of the discharge curves shows pseudocapacitance similar to the result of the CV curves. The specific capacitances of the sample at the current density of 5 mA cm$^{-2}$ was 840 F g$^{-1}$. 
Energy density and power density analysis. Energy density of the electrode can be derived from the CV curves using the following equation:

\[ ED = \frac{1}{2} \cdot C_{sp} \cdot \Delta V^2 \] (5)

where \( C_{sp} \) is specific capacitance (F) and \( \Delta V \) is the potential window (V).\(^8,^9\) The power density of the electrode can be calculated from the following equation:

\[ PD = \frac{ED}{\Delta t} \] (6)

where \( ED \) is the energy density, and \( \Delta t \) is the discharge time (s).\(^9\) The energy density of the composite film was about 38.9 Wh kg\(^{-1}\) at the scan rate of 1 mV s\(^{-1}\), whereas its power density was approximately 21 kW kg\(^{-1}\) at 1000 mV s\(^{-1}\). We also calculated the energy and power densities of other materials to compare with those of our material.\(^5,^{10,11,12}\) The result is shown in Fig. S5. In fact, in previous studies, the electrochemical properties were already saturated. However, in our study on composite material electrodes made by the co-precipitation method, the electrochemical properties were similar or better.
